The hard processor system (HPS) provides two UART controllers for asynchronous serial communication. The UART controllers are based on an industry standard 16550 UART controller. The UART controllers are instances of the Synopsys DesignWare APB Universal Asynchronous Receiver/Transmitter (DW_apb_uart) peripheral.⁽⁶³⁾

UART Controller Features

The UART controller provides the following functionality and features:

- Programmable character properties, such as number of data bits per character, optional parity bits, and number of stop bits †
- Line break generation and detection †
- Direct memory access (DMA) controller interface
- Prioritized interrupt identification †
- Programmable baud rate
- False start bit detection †
- Automatic flow control mode per 16750 standard †
- Internal loopback mode support
- 128-byte transmit and receive FIFO buffers
 - FIFO buffer status registers †
 - FIFO buffer access mode (for FIFO buffer testing) enables write of receive FIFO buffer by master and read of transmit FIFO buffer by master †
- Shadow registers reduce software overhead and provide programmable reset †
- Transmitter holding register empty (THRE) interrupt mode †

UART Controller Block Diagram and System Integration

Figure 22-1: UART Block Diagram

Table 22-1: UART Controller Block Descriptions

Block	Description
Slave interface	Slave interface between the component and L4 peripheral bus.
Register block	Provides main UART control, status, and interrupt generation functions.†
FIFO buffer	Provides FIFO buffer control and storage. †
Baud clock generator	Generates the transmitter and receiver baud clock. With a reference clock of 100 MHz, the UART controller supports transfer rates of 95 baud to 6.25 Mbaud. This supports communication with all known 16550 devices. The baud rate is controlled by programming the interrupt enable or divisor latch high (IER_DLH) and receive buffer, transmit holding, or divisor latch low (RBR_THR_DLL) registers.
Serial transmitter	Converts parallel data written to the UART into serial data and adds all additional bits, as specified by the control register, for transmission. This makeup of serial data, referred to as a character, exits the block in serial UART. †

Block	Description
Serial receiver	Converts the serial data character (as specified by the control register) received in the UART format to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block. †
DMA interface	The UART controller includes a DMA controller interface to indicate when received data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports single and burst transfers. You can use DMA in FIFO buffer and non-FIFO buffer mode.

uart_dtr	1 bit	Output	Data terminal ready
uart_out1_n	1 bit	Output	User defined output 1
uart_out2_n	1 bit	Output	User defined output 2

Functional Description of the UART Controller

The HPS UART is based on an industry-standard 16550 UART. The UART supports serial communication with a peripheral, modem (data carrier equipment), or data set. The master (CPU) writes data over the slave bus to the UART. The UART converts the data to serial format and transmits to the destination device. The UART also receives serial data and stores it for the master (CPU). †

The UART's registers control the character length, baud rate, parity generation and checking, and interrupt generation. The UART's single interrupt output signal is supported by several prioritized interrupt types that trigger assertion. You can separately enable or disable each of the interrupt types with the control registers. †

FIFO Buffer Support

The UART controller includes 128-byte FIFO buffers to buffer transmit and receive data. FIFO buffer access mode allows the master to write the receive FIFO buffer and to read the transmit FIFO buffer for test purposes. FIFO buffer access mode is enabled with the FIFO access register (FAR). Once enabled, the control portions of the transmit and receive FIFO buffers are reset and the FIFO buffers are treated as empty. †

When FIFO buffer access mode is enabled, you can write data to the transmit FIFO buffer as normal; however, no serial transmission occurs in this mode and no data leaves the FIFO buffer. You can read back the data that is written to the transmit FIFO buffer with the transmit FIFO read (TFR) register. The TFR register provides the current data at the top of the transmit FIFO buffer. †

Similarly, you can also read data from the receive FIFO buffer in FIFO buffer access mode. Since the normal operation of the UART is halted in this mode, you must write data to the receive FIFO buffer to read it back. The receive FIFO write (RFW) register writes data to the receive FIFO buffer. The upper two bits of the 10-bit register write framing errors and parity error detection information to the receive FIFO buffer. Bit 9 of RFW indicates a framing error and bit 8 of RFW indicates a parity error. Although you cannot read these bits back from the receive buffer register, you can check the bits by reading the line status register (LSR), and by checking the corresponding bits when the data in question is at the top of the receive FIFO buffer. †

UART(RS232) Serial Protocol

Because the serial communication between the UART controller and the selected device is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. Utilizing these bits allows two devices to be synchronized. This structure of serial data accompanied by start and stop bits is referred to as a character, as shown in below.†

Figure 22-2: Serial Data Format

An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to provide the UART controller with the ability to perform simple error checking on the received data.†

The Control Register is used to control the serial character characteristics. The individual bits of the data word are sent after the start bit, starting with the least- significant bit (LSB). These are followed by the optional parity bit, followed by the stop bit(s), which can be 1, 1.5 or 2.†

All the bits in the transmission (with exception to the half stop bit when 1.5 stop bits are used) are transmitted for exactly the same time duration. This is referred to as a Bit Period or Bit Time. One Bit Time equals 16 baud clocks. To ensure stability on the line, the receiver samples the serial input data at approximately the midpoint of the Bit Time once the start bit has been detected. Because the exact number of baud clocks that each bit transmission is known, calculating the midpoint for sampling is not difficult. That is, every 16 baud clocks after the midpoint sample of the start bit.†

Together with serial input debouncing, this feature also contributes to avoid the detection of false start bits. Short glitches are filtered out by debouncing, and no transition is detected on the line. If a glitch is wide enough to avoid filtering by debouncing, a falling edge is detected. However, a start bit is detected only if the line is sampled low again after half a bit time has elapsed. †

Figure 22-3: Receiver Serial Data Sample Points

The baud rate of the UART controller is controlled by the serial clock and the Divisor Latch Register (DLH and DLL).†

Automatic Flow Control

The UART includes 16750-compatible request-to-send (RTS) and clear-to-send (CTS) serial data automatic flow control mode. You enable automatic flow control with the modem control register (MCR.AFCE). †

Automatic RTS mode

Automatic RTS mode becomes active when the following conditions occur: †

- RTS (`MCR.RTS` bit and `MCR.AFCE` bit are both set)
- FIFO buffers are enabled (`FCR.FIFOE` bit is set)

When `rts_n` is connected to the `cts_n` input pin of another UART device, the other UART stops sending serial data until the receive FIFO buffer has available space (until it is completely empty). †

The selectable receive FIFO buffer threshold values are 1, $\frac{1}{4}$, $\frac{1}{2}$, and 2 less than full. Because one additional character may be transmitted to the UART after `rts_n` is inactive (due to data already having entered the transmitter block in the other UART), setting the threshold to 2 less than full allows maximum use of the FIFO buffer with a margin of one character. †

Once the receive FIFO buffer is completely emptied by reading the receiver buffer register (`RBR_THR_DLL`), `rts_n` again becomes active (low), signaling the other UART to continue sending data. †

Even when you set the correct `MCR` bits, if the FIFO buffers are disabled through `FCR.FIFOE`, automatic flow control is also disabled. When auto RTS is not implemented or disabled, `rts_n` is controlled solely by `MCR.RTS`. In the Automatic RTS Timing diagram, the character `T` is received because `rts_n` is not detected prior to the next character entering the sending UART transmitter. †

Figure 22-4: Automatic RTS Timing

Automatic CTS mode

Automatic CTS mode becomes active when the following conditions occur: †

- AFCE (`MCR.AFCE` bit is set)
- FIFO buffers are enabled (through FIFO buffer control register `IIR_FCR.FIFOE`) bit

When automatic CTS is enabled (active), the UART transmitter is disabled whenever the `cts_n` input becomes inactive (high). This prevents overflowing the FIFO buffer of the receiving UART. †

If the `cts_n` input is not deactivated before the middle of the last stop bit, another character is transmitted before the transmitter is disabled. While the transmitter is disabled, you can continue to write and even overflow to the transmit FIFO buffer. †

Automatic CTS mode requires the following sequence:

1. The UART status register are read to verify that the transmit FIFO buffer is full (UART status register `USR.TFNF` set to zero). †
2. The current FIFO buffer level is read via the transmit FIFO level (`TFL`) register. †
3. Programmable THRE interrupt mode must be enabled to access the FIFO buffer full status from the LSR. †

When using the FIFO buffer full status, software can poll this before each write to the transmit FIFO buffer. When the `cts_n` input becomes active (low) again, transmission resumes. If the FIFO buffers are disabled with the `FCR.FIFOE` bit, automatic flow control is also disabled regardless of any other settings. When auto CTS is not implemented or disabled, the transmitter is unaffected by `cts_n`.†

Figure 22-5: Automatic CTS Timing

Clocks

The UART controller is connected to the `l4_sp_clk` clock. The clock input is driven by the clock manager.

Related Information

[Clock Manager](#) on page 3-1

For more information, refer to the *Clock Manager* chapter.

Resets

The UART controller is connected to the `uart_rst_n` reset signal. The reset manager drives the signal on a cold or warm reset.

Taking the UART Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to the *Reset Manager* chapter.

Interrupts

The assertion of the UART interrupt output signal occurs when one of the following interrupt types are enabled and active: †

Table 22-4: Interrupt Types and Priority †

Interrupt Type	Priority	Source	Interrupt Reset Control
Receiver line status	Highest	Overrun, parity and framing errors, break condition.	Reading the line status Register.

Interrupt Type	Priority	Source	Interrupt Reset Control
Received data available	Second	Receiver data available (FIFOs disabled) or RCVR FIFO trigger level reached (FIFOs enabled).	Reading the receiver buffer register (FIFOs disabled) or the FIFO drops below the trigger level (FIFOs enabled)
Character timeout indication	Second	No characters in or out of the Receive FIFO during the last 4 character times and there is at least 1 character in it during this Time.	Reading the receiver buffer Register.
Transmit holding register empty	Third	Transmitter holding register empty (Programmable THRE Mode disabled) or Transmit FIFO at or below threshold (Programmable THRE Mode enabled).	Reading the IIR register (if source of interrupt); or, writing into THR (FIFOs or Programmable THRE Mode not enabled) or Transmit FIFO above threshold (FIFOs and Programmable THRE Mode enabled).
Modem Status	Fourth	Clear to send or data set ready or ring indicator or data carrier detect. If auto flow control mode is enabled, a change in CTS (that is, DCTS set) does not cause an interrupt.	Reading the Modem status Register.

You can enable the interrupt types with the interrupt enable register (`IER_DLH`).

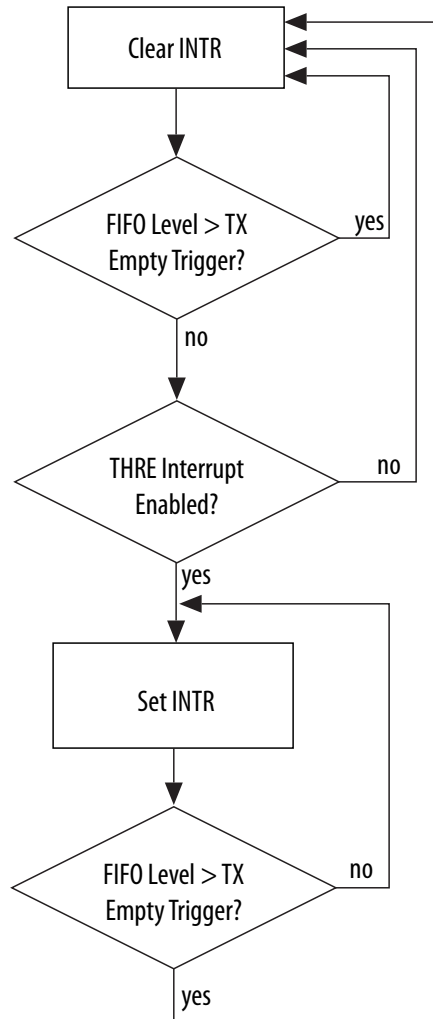

Note: "Received Data Available" and "Character Timeout Indication" are enabled by a single bit in the `IER_DLH` register, because they have the same priority.

Once an interrupt is signaled, you can determine the interrupt source by reading the Interrupt Identity Register (IIR).

Programmable THRE Interrupt

The UART has a programmable THRE interrupt mode to increase system performance. You enable the programmable THRE interrupt mode with the interrupt enable register (`IER_DLH.PTIME`). When the THRE mode is enabled, THRE interrupts and the `dma_tx_req` signal are active at and below a programmed transmit FIFO buffer empty threshold level, as shown in the flowchart. †

Figure 22-6: Programmable THRE Interrupt

The threshold level is programmed into `FCR.TET`. The available empty thresholds are empty, 2, $\frac{1}{4}$, and $\frac{1}{2}$. The optimum threshold value depends on the system's ability to begin a new transmission sequence in a timely manner. However, one of these thresholds should prove optimum in increasing system performance by preventing the transmit FIFO buffer from running empty.

In addition to the interrupt change, line status register (`LSR.THRE`) also switches from indicating that the transmit FIFO buffer is empty, to indicating that the FIFO buffer is full. This change allows software to fill the FIFO buffer for each transmit sequence by polling `LSR.THRE` before writing another character. This directs the UART to fill the transmit FIFO buffer whenever an interrupt occurs and there is data to transmit, instead of waiting until the FIFO buffer is completely empty. Waiting until the FIFO buffer is empty reduces performance whenever the system is too busy to respond immediately. You can increase system efficiency when this mode is enabled in combination with automatic flow control.

When not selected or disabled, THRE interrupts and `LSR.THRE` function normally, reflecting an empty THRE or FIFO buffer.

Figure 22-7: Interrupt Generation without Programmable THRE Interrupt Mode

DMA Controller Operation

The UART controller includes a DMA controller interface to indicate when the receive FIFO buffer data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports both single and burst transfers.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the UART controller is 128 entries.

Related Information

[DMA Controller](#) on page 17-1

For more information, refer to the DMA Controller chapter.

Transmit FIFO Underflow

During UART serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the decoded level of the Transmit Empty Trigger (TET) field in the FIFO Control Register (FCR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of data (underflow) causing a STOP to be inserted on the UART bus. To prevent this condition, you must set the watermark level correctly. †

Related Information

[DMA Controller](#) on page 17-1

For more information, refer to the DMA Controller chapter.

Transmit Watermark Level

Consider the example where the following assumption is made: †

DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

IIR_FCR.TET = 1

IIR_FCR.TET = 1 decodes to a watermark level of 16.

- Transmit FIFO watermark level = decoded watermark level of IIR_FCR.TET = 16 †
- DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET = 112 †
- UART transmit FIFO_DEPTH = 128 †
- Block transaction size = 448 †

Figure 22-8: Transmit FIFO Watermark Level = 16

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 448/112 = 4$$

The number of burst transactions in the DMA block transfer is 4. But the watermark level, decoded level of `IIR_FCR.TET`, is quite low. Therefore, the probability of transmit underflow is high where the UART serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

IIR_FCR.TET = 3

`IIR_FCR.TET = 3` decodes to a watermark level of 64.

- Transmit FIFO watermark level = decoded watermark level of `IIR_FCR.TET` = 64 †
- DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET` = 64 †
- UART transmit `FIFO_DEPTH` = 128 †
- Block transaction size = 448 †

Figure 22-9: Transmit FIFO Watermark Level = 64

Number of burst transactions in block: †

Block transaction size/DMA burst length = $448/64 = 7$ †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, decoded level of `IIR_FCR.TET`, is high. Therefore, the probability of UART transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the UART transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the UART transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length \leq `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET`

In case 2: decoded watermark level of `IIR_FCR.TET` = 64, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length must be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET`

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the UART controller has successfully transmitted one data item or more on the UART serial transmit line during the transfer. †

Receive FIFO Overflow

During UART serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the decoded level of Receive Trigger (`RT`) field in the FIFO Control Register (`IIR_FCR`). This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, decoded watermark level of `IIR_FCR.RT`, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a tradeoff between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = decoded watermark level of `IIR_FCR.RT` + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, decoded watermark level of `IIR_FCR.RT`. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

The receive FIFO will not be empty at the end of the source burst transaction if the UART controller has successfully received one data item or more on the UART serial receive line during the burst. †

Figure 22-10: Receive FIFO Buffer

UART Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

rbr_thr_dll Fields

Bit	Name	Description	Access	Reset
7:0	value	<p>Receive Buffer Register: This register contains the data byte received on the serial input port (uart_rxd). The data in this register is valid only if the Data Ready (bit [0] in the Line Status Register(LSR)) is set to 1. If FIFOs are disabled(bit[0] of Register FCR is set to 0) the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled(bit [0] of Register FCR is set to 1) this register accesses the head of the receive FIFO. If the receive FIFO is full, and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur.</p> <p>Transmit Holding Register: This register contains data to be transmitted on the serial output port. Data should only be written to the THR when the THR Empty bit [5] of the LSR Register is set to 1. If FIFOs are disabled (bit [0] of Register FCR) is set to 0 and THRE is set to 1, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of Register FCR is set to 1 and THRE is set up to 128 characters of data may be written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost.</p> <p>Divisor Latch Low: This register makes up the lower 8-bits of a 16-bit, Read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 1. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor) Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.</p>	RW	0x0

ier_dlh

This is a multi-function register. This register enables/disables receive and transmit interrupts and also controls the most-significant 8-bits of the baud rate divisor. Divisor Latch High Register: This register is accessed when the DLAB bit [7] of the LCR Register is set to 1. Bits[7:0] contain the high order 8-bits of the baud rate divisor. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor): Note that

with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 $l4_sp_clk$ clock cycles should be allowed to pass before transmitting or receiving data. Interrupt Enable Register: This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 0. Allows control of the Interrupt Enables for transmit and receive functions.

Bit	Name	Description	Access	Reset						
7	rfe	<p>This bit is only relevant when FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no error in Rx FIFO</td> </tr> <tr> <td>0x1</td> <td>error in Rx FIFO</td> </tr> </tbody> </table>	Value	Description	0x0	no error in Rx FIFO	0x1	error in Rx FIFO	RO	0x0
Value	Description									
0x0	no error in Rx FIFO									
0x1	error in Rx FIFO									

Bit	Name	Description	Access	Reset						
6	temt	<p>If in FIFO mode and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmit Empty not set</td> </tr> <tr> <td>0x1</td> <td>Transmit Empty set</td> </tr> </tbody> </table>	Value	Description	0x0	Transmit Empty not set	0x1	Transmit Empty set	RO	0x1
Value	Description									
0x0	Transmit Empty not set									
0x1	Transmit Empty set									
5	thre	<p>If THRE mode is disabled (IER[7] set to zero) this bit indicates that the THR or Tx FIFO is empty. This bit is set whenever data is transferred from the THR or Tx FIFO to the transmitter shift register and no new data has been written to the THR or Tx FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If both THRE and FIFOs are enabled, both (IER[7] set to one and FCR[0] set to one respectively), the functionality will indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] thresholdsetting.</p>	RO	0x1						
4	bi	<p>This is used to indicate the detection of a break sequence on the serial input data. Set whenever the serial input, sin, is held in a logic 0 state for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. The character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit.</p>	RO	0x0						

Bit	Name	Description	Access	Reset						
3	fe	<p>This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit(LSR[3]) will be set if a break interrupt has occurred, as indicated by a Break Interrupt BIT bit (LSR[4]). Reading the LSR clears the FE bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no framing error</td> </tr> <tr> <td>0x1</td> <td>framing error</td> </tr> </tbody> </table>	Value	Description	0x0	no framing error	0x1	framing error	RO	0x0
Value	Description									
0x0	no framing error									
0x1	framing error									
2	pe	<p>This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. Since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). Reading the LSR clears the PE bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no parity error</td> </tr> <tr> <td>0x1</td> <td>no parity error</td> </tr> </tbody> </table>	Value	Description	0x0	no parity error	0x1	no parity error	RO	0x0
Value	Description									
0x0	no parity error									
0x1	no parity error									

Bit	Name	Description	Access	Reset						
1	oe	<p>This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. Reading the LSR clears the OE bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no overrun error</td> </tr> <tr> <td>0x1</td> <td>overrun error</td> </tr> </tbody> </table>	Value	Description	0x0	no overrun error	0x1	overrun error	RO	0x0
Value	Description									
0x0	no overrun error									
0x1	overrun error									
0	dr	<p>This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no data ready</td> </tr> <tr> <td>0x1</td> <td>data ready</td> </tr> </tbody> </table>	Value	Description	0x0	no data ready	0x1	data ready	RO	0x0
Value	Description									
0x0	no data ready									
0x1	data ready									

msr

It should be noted that whenever bits 0, 1, 2 or 3 are set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

srbr Fields

Bit	Name	Description	Access	Reset
7:0	srbr	This is a shadow register for the RBR and has been allocated one 32-bit location so as to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin). The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If FIFOs are disabled, bit [0] of register FCR set to zero, the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur.	RW	0x0

sth

Used to accomadate burst accesses from the master.

Module Instance	Base Address	Register Address

sth Fields

Bit	Name	Description	Access	Reset
7:0	sth	This is a shadow register for the THR and has been allocated sixteen 32-bit locations so as to accommodate burst accesses from the master. This register contains data to be transmitted on the serial output port (sout). Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If FIFO's are disabled bit [0] of register FCR set to zero and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of register FCR set to one and THRE is set, 128 characters of data may be written to the THR before the FIFO is full. The UART FIFO depth is configured for 128 characters. Any attempt to write data when the FIFO is full results in the write data being lost.	RW	0x0

far

This register is used in FIFO access testing.

Module Instance	Base Address	Register Address

The hard processor system (HPS) provides three general-purpose I/O (GPIO) interface modules. The GPIO modules are instances of the Synopsys DesignWare APB General Purpose Programming I/O (DW_apb_gpio) peripheral.† ⁽⁶⁴⁾

Features of the GPIO Interface

The GPIO interface offers the following features:

- Supports digital debounce
- Configurable interrupt mode
- Supports up to 67 I/O pins and 14 input-only pins

GPIO Interface Block Diagram and System Integration

The figure below shows a block diagram of the GPIO interface. The following table shows a pin table of the GPIO interface:

Figure 23-1: Cyclone V SoC GPIO

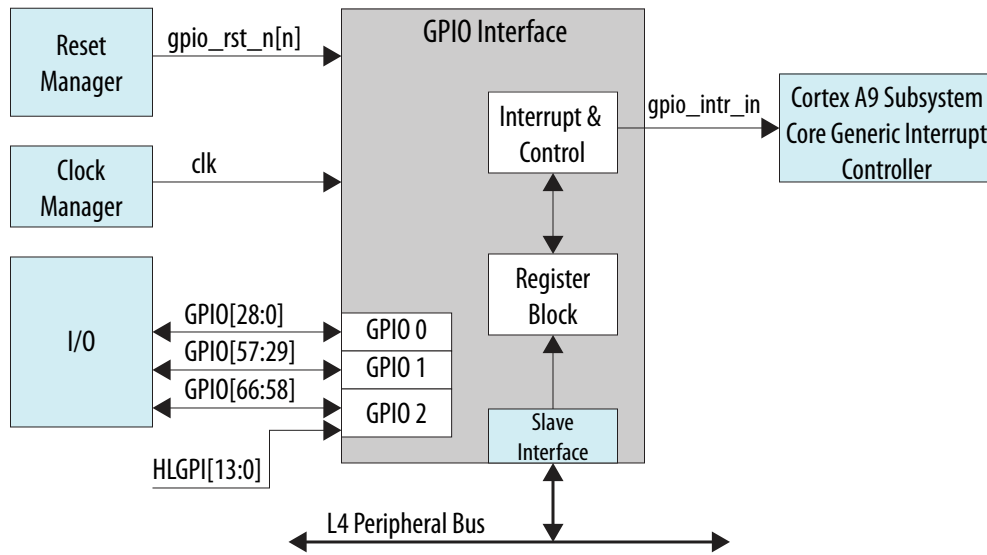

Table 23-1: GPIO Interface pin table

Pin Name	Mapped to GPIO Signal Name	Comments
GPIO [28:0]	GPIO 0 [28:0]	Input / Output
GPIO [57:29]	GPIO 1 [28:0]	Input / Output
GPIO [66:58]	GPIO 2 [8:0]	Input / Output
HLGPI [13:0]	GPIO 2 [26:13]	Input only

For more information on I/O banks locations on device, refer to *Cyclone V I/O Features*.

Functional Description of the GPIO Interface

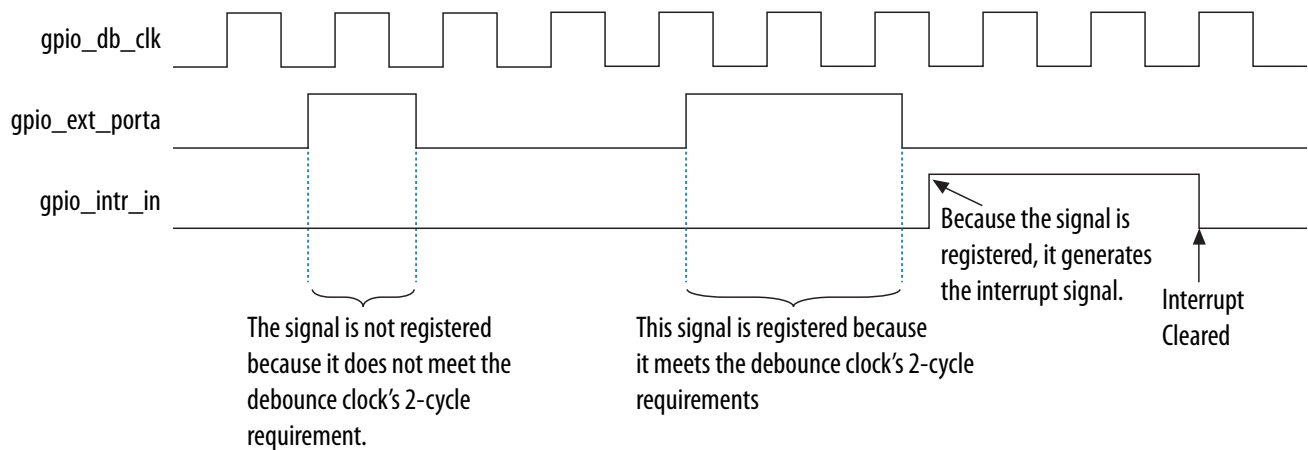

Debounce Operation

The GPIO modules provided in the HPS include optional debounce capabilities. The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock, `gpio_db_clk`. †

When input signals are debounced using the `gpio_db_clk` debounce clock, the signals must be active for a minimum of two cycles of the debounce clock to guarantee that they are registered. Any input pulse widths less than a debounce clock period are filtered out. If the input signal pulse width is between one and two debounce clock widths, it may or may not be filtered out, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered. †

The figure below shows a timing diagram of the debounce circuitry for both cases: a bounced input signal, and later, a propagated input signal.

Figure 23-2: Debounce Timing With Asynchronous Reset Flip-Flops

Note: Enabling the debounce circuitry increases interrupt latency by two clock cycles of the debounce clock.

Pin Directions

The pins `GPIO0` through `GPIO66` can be configured to be either input or output signals. The pins `HLGPIO` through `HLGPIO13` share pins with the HPS DDR controller and are input-only signals.

Taking the GPIO Interface Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

GPIO Pin State During Reset

Ensure you understand the state of the GPIO during a warm or cold reset.

Cold reset: HPS I/O are in tri-state with a weak pull-up. The pin multiplexer and the GPIO/LoanIO multiplexer are in the default state meaning they are set to their reset value. You can find the default, reset value in the registers of the `Pin Mux Control Group`.

Warm reset: HPS I/O retain their configuration. The pin multiplexer and GPIO/LoanIO Multiplexer do not change configuration during warm reset meaning they are not reset to the default, reset value but maintain the current settings. For example, the pin multiplexer determines which signals go to the pins.

Thus, if a pin multiplexer is set to be a GPIO it remains as a GPIO after warm reset. And when warm reset is triggered, the GPIO block is reset and the GPIO data direction register (`gpio_swporta_ddr`) is reset to 0x0 which is input, meaning the HPS I/O are inputs. In summary, a warm reset retains the pin multiplexer configuration but not the direction and output level which is controlled by the GPIO block. This block is reset under warm reset.

GPIO Interface Programming Model

Debounce capability for each of the input signals can be enabled or disabled under software control by setting the corresponding bits in the `gpio_debounce` register, accordingly. The debounce clock must be stable and operational before the debounce capability is enabled.

Under software control, the direction of the external I/O pad is controlled by a write to the `gpio_swportx_ddr` register. When configured as input mode, reading `gpio_ext_porta` would read the values on the signal of the external I/O pad. When configured as output mode, the data written to the `gpio_swporta_dr` register drives the output buffer of the I/O pad. The same pins are shared for both input and output modes, so they cannot be configured as input and output modes at the same time. †

General-Purpose I/O Interface Address Map and Register Definitions

The address map and register definitions for the GPIO consist of the following regions:

- GPIO Module 0
- GPIO Module 1
- GPIO Module 2

gpio_inten RW 0x0															

gpio_inten Fields

Bit	Name	Description	Access	Reset						
28:0	gpio_inten	Allows each bit of Port A Data Register to be configured for interrupt capability. Interrupts are disabled on the corresponding bits of Port A Data Register if the corresponding data direction register is set to Output. Note that only bits[26:0] are implemented for gpio2. <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Disable Interrupt on Port A</td></tr> <tr> <td>0x1</td><td>Enable Interrupt on Port A</td></tr> </tbody> </table>	Value	Description	0x0	Disable Interrupt on Port A	0x1	Enable Interrupt on Port A	RW	0x0
Value	Description									
0x0	Disable Interrupt on Port A									
0x1	Enable Interrupt on Port A									

gpio_intmask

Controls which pins cause interrupts on Port A Data Register inputs.

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF708034
gpio1	0xFF709000	0xFF709034
gpio2	0xFF70A000	0xFF70A034

Offset: 0x34

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved			gpio_intmask RW 0x0												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpio_intmask RW 0x0															

gpio_intmask Fields

Bit	Name	Description	Access	Reset						
28:0	gpio_intmask	<p>Controls whether an interrupt on Port A Data Register can generate an interrupt to the interrupt controller by not masking it. The unmasked status can be read as well as the resultant status after masking. Note that only bits[26:0] are implemented for gpio2.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Interrupt bits are unmasked</td> </tr> <tr> <td>0x1</td> <td>Mask Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	Interrupt bits are unmasked	0x1	Mask Interrupt	RW	0x0
Value	Description									
0x0	Interrupt bits are unmasked									
0x1	Mask Interrupt									

gpio_inttype_level

The interrupt level register defines the type of interrupt (edge or level).

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF708038
gpio1	0xFF709000	0xFF709038
gpio2	0xFF70A000	0xFF70A038

Offset: 0x38

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpio_raw_intstatus RO 0x0															

gpio_raw_intstatus Fields

Bit	Name	Description	Access	Reset						
28:0	gpio_raw_intstatus	Raw interrupt of status of Port A Data Register (premasking bits). Note that only bits[26:0] are implemented for gpio2.	RO	0x0						
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Inactive</td> </tr> <tr> <td>0x1</td> <td>Active</td> </tr> </tbody> </table>	Value	Description	0x0	Inactive	0x1	Active		
Value	Description									
0x0	Inactive									
0x1	Active									

gpio_debounce

Debounces each IO Pin

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF708048
gpio1	0xFF709000	0xFF709048
gpio2	0xFF70A000	0xFF70A048

Offset: 0x48

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved			gpio_debounce RW 0x0												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpio_debounce RW 0x0															

gpio_debounce Fields

Bit	Name	Description	Access	Reset						
28:0	gpio_debounce	Controls whether an external signal that is the source of an interrupt needs to be debounced to remove any spurious glitches. A signal must be valid for two periods of an external clock (gpio_db_clk) before it is internally processed. Note that only bits[26:0] are implemented for gpio2. <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>No debounce</td></tr> <tr> <td>0x1</td><td>Enable debounce</td></tr> </tbody> </table>	Value	Description	0x0	No debounce	0x1	Enable debounce	RW	0x0
Value	Description									
0x0	No debounce									
0x1	Enable debounce									

gpio_porta_eoi

Port A Data Register interrupt handling.

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF70804C
gpio1	0xFF709000	0xFF70904C
gpio2	0xFF70A000	0xFF70A04C

Offset: 0x4C

Access: WO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

The hard processor system (HPS) provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus. The timers optionally generate an interrupt when the 32-bit binary count-down timer reaches zero. The timers are instances of the Synopsys DesignWare APB Timers (DW_apb_timers) peripheral. ⁽⁶⁵⁾

Related Information

[Cortex-A9 Microprocessor Unit Subsystem](#) on page 10-1

The MPU subsystem provides additional timers. For more information about the timers in the MPU, refer to the *Cortex-A9 MPU* chapter.

Features of the Timer

- Supports interrupt generation
- Supports free-running mode
- Supports user-defined count mode

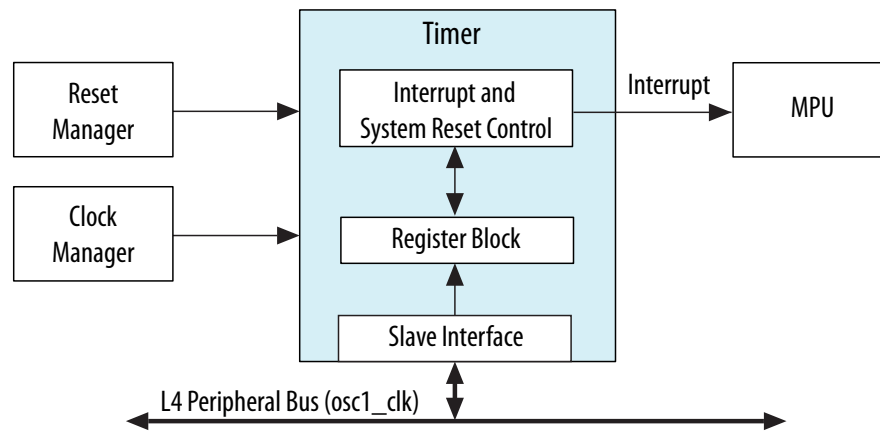

Timer Block Diagram and System Integration

Each timer includes a slave interface for control and status register (CSR) access, a register block, and a programmable 32-bit down counter that generates interrupts on reaching zero. The timer operates on a single clock domain driven by the clock manager.

Figure 24-1: Timer Block Diagram

Functional Description of the Timer

The 32-bit timer counts down from a programmed value and generates an interrupt when the count reaches zero. The timer has an independent clock input connected to the system clock signal or to an external clock source. †

The timer supports the following modes of operation:

- Free-running mode—decrementing from the maximum value (0xFFFFFFFF). Reloads maximum value upon reaching zero.
- User-defined count mode—generates a periodic interrupt. Decrements from the user-defined count value loaded from the timer1 load count register (`timer1loadcount`). Reloads the user-defined count upon reaching zero.

The initial value for the timer (that is, the value from which it counts down) is loaded into the timer by the `timer1loadcount` register. The following events can cause a timer to load the initial count from the `timer1loadcount` register: †

- Timer is enabled after being reset or disabled
- Timer counts down to 0

Clocks

Table 24-1: Timer Clock Characteristics

Timer	System Clock	Notes
OSC1 timer 0	osc1_clk	—
OSC1 timer 1		
SP timer 0	l4_sp_clk	Timer must be disabled if clock frequency changes
SP timer 1		

The timers above are labeled according to the clock it receives. OSC timers receive the oscillator clock `osc1_clk` and the SP timers receives the l4 slave peripheral clock `l4_sp_clk`.

SP timer 0 and SP timer 1 must be disabled before `l4_sp_clk` is changed to another frequency. You can then re-enable the timer once the clock frequency change takes effect. You cannot change the frequency of OSC1 timer 0 and OSC1 timer 1.

Related Information

[Clock Manager](#) on page 3-1

For more information about clock performance, refer to the *Clock Manager* chapter.

Resets

The timers are reset by a cold or warm reset. Resetting the timers produces the following results in the following order:

1. The timer is disabled.
2. The interrupt is enabled.
3. The timer enters free-running mode.
4. The timer count load register value is set to zero.

Interrupts

The timer1 interrupt status (`timer1intstat`) and timer1 end of interrupt (`timer1eoi`) registers handle the interrupts. The `timer1intstat` register allows you to read the status of the interrupt. Reading from the `timer1eoi` register clears the interrupt. †

The timer1 control register (`timer1controlreg`) contains the timer1 interrupt mask bit (`timer1_interrupt_mask`) to mask the interrupt. In both the free-running and user-defined count modes of operation, the timer generates an interrupt signal when the timer count reaches zero and the interrupt mask bit of the control register is high.

If the timer interrupt is set, then it is cleared when the timer is disabled.

FPGA Interface

The timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Platform Designer (Standard).

Related Information

[Interrupts](#) on page 28-5

For more information about configuring and routing timer interrupts, refer to the interrupt section of the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

Timer Programming Model

Initialization

To initialize the timer, perform the following steps: †

1. Initialize the timer through the `timer1controlreg` register: †
 - Disable the timer by writing a 0 to the timer1 enable bit (`timer1_enable`) of the `timer1controlreg` register. †
- Note:** Before writing to a timer1 load count register (`timer1loadcount`), you must disable the timer by writing a 0 to the `timer1_enable` bit of the `timer1controlreg` register to avoid potential synchronization problems. †
- Program the timer mode—user-defined count or free-running—by writing a 0 or 1, respectively, to the timer1 mode bit (`timer1_mode`) of the `timer1controlreg` register. †
 - Set the interrupt mask as either masked or not masked by writing a 1 or 0, respectively, to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †
2. Load the timer counter value into the `timer1loadcount` register. †
 3. Enable the timer by writing a 1 to the `timer1_enable` bit of the `timer1controlreg` register. †

Enabling the Timer

When a timer transitions to the enabled state, the current value of `timer1loadcount` register is loaded into the timer counter. †

1. To enable the timer, write a 1 to the `timer1_enable` bit of the `timer1controlreg` register.

Disabling the Timer

When the timer enable bit is cleared to 0, the timer counter and any associated registers in the timer clock domain, are asynchronously reset. †

1. To disable the timer, write a 0 to the `timer1_enable` bit. †

Loading the Timer Countdown Value

When a timer counter is enabled after being reset or disabled, the count value is loaded from the `timer1loadcount` register; this occurs in both free-running and user-defined count modes. †

When a timer counts down to 0, it loads one of two values, depending on the timer operating mode: †

- User-defined count mode—timer loads the current value of the `timer1loadcount` register. Use this mode if you want a fixed, timed interrupt. Designate this mode by writing a 1 to the `timer1_mode` bit of the `timer1controlreg` register. †
- Free-running mode—timer loads the maximum value (0xFFFFFFFF). The timer max count value allows for a maximum amount of time to reprogram or disable the timer before another interrupt occurs. Use this mode if you want a single timed interrupt. Enable this mode by writing a 0 to the `timer1_mode` bit of the `timer1controlreg` register. †

Servicing Interrupts

Clearing the Interrupt

An active timer interrupt can be cleared in two ways.

1. If you clear the interrupt at the same time as the timer reaches 0, the interrupt remains asserted. This action happens because setting the timer interrupt takes precedence over clearing the interrupt. †
2. To clear an active timer interrupt, read the `timer1eoi` register or disable the timer. When the timer is enabled, its interrupt remains asserted until it is cleared by reading the `timer1eoi` register. †

Checking the Interrupt Status

You can query the interrupt status of the timer without clearing its interrupt.

1. To check the interrupt status, read the `timer1intstat` register. †

Masking the Interrupt

The timer interrupt can be masked using the `timer1controlreg` register.

To mask an interrupt, write a 1 to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- OSC1 Timer Module 0
- OSC1 Timer Module 1
- SP Timer Module 0
- SP Timer Module 1

The watchdog timers are peripherals you can use to recover from system lockup that might be caused by software or system related issues. The hard processor system (HPS) provides two programmable watchdog timers, which are connected to the level 4 (L4) peripheral bus. The watchdog timers are instances of the Synopsys DesignWare APB Watchdog Timer (DW_apb_wdt) peripheral. ⁽⁶⁶⁾

The microprocessor unit (MPU) subsystem provides two additional watchdog timers.

Related Information

For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

Features of the Watchdog Timer

The following list describes the features of the watchdog timer:

- Programmable 32-bit timeout range
- Timer counts down from a preset value to zero, then performs one of the following user-configurable operations:
 - Generates a system reset †
 - Generates an interrupt, restarts the timer, and if the timer is not cleared before a second timeout occurs, generates a system reset
- Dual programmable timeout period, used when the time to wait after the first start is different than that required for subsequent restarts †
- Prevention of accidental restart of the watchdog counter †
- Prevention of accidental disabling of the watchdog counter †
- Pause mode for debugging

Watchdog Timer Block Diagram and System Integration

Each watchdog timer consists of a slave interface for control and status register (CSR) access, a register block, and a 32-bit down counter that operates on the slave interface clock (`osc1_clk`). A pause input, driven by the system manager, optionally pauses the counter when a CPU is being debugged.

The watchdog timer drives an interrupt request to the MPU and a reset request to the reset manager.

Functional Description of the Watchdog Timer

Watchdog Timer Counter

Each watchdog timer is a programmable, little-endian down counter that decrements by one on each clock cycle. The watchdog timer supports 16 fixed timeout period values. Software chooses which timeout periods are desired. A timeout period is $2^{<n>}$ `osc1_clk` clock periods, where n is an integer from 16 to 31 inclusive.

Software must regularly restart the timer (which reloads the counter with the restart timeout period value) to indicate that the system is functioning normally. Software can reload the counter at any time by writing to the restart register. If the counter reaches zero, the watchdog timer has timed out, indicating an unrecoverable error has occurred and a system reset is needed.

Software configures the watchdog timer to one of the following output response modes:

- On timeout, generate a reset request.
- On timeout, assert an interrupt request and restart the watchdog timer. Software must service the interrupt and reset the watchdog timer before a second timeout occurs. Otherwise, generate a reset request.

If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

Note: After the watchdog timer reaches zero and generates a reset or interrupt, the counter resets and continues to count.

- [Setting the Timeout Period Values](#) on page 25-4
- [Selecting the Output Response Mode](#) on page 25-4
- [Reloading a Watchdog Counter](#) on page 25-5

Watchdog Timer Pause Mode

The watchdog timers can be paused during debugging. The watchdog timer pause mode is controlled by the system manager. The following options are available:

- Pause the timer while either CPU0 or CPU1 is in debug mode
- Pause the timer while only CPU1 is in debug mode
- Pause the timer while only CPU0 is in debug mode
- Do not pause the timer

When pause mode is enabled, the system manager pauses the watchdog timer while debugging. When pause mode is disabled, the watchdog timer runs while debugging.

At reset, the watchdog pausing feature is enabled for both CPUs by default.

Related Information

[Pausing a Watchdog Timer](#) on page 25-5

Watchdog Timer Clocks

Each watchdog timer is connected to the `osc1_clk` clock so that timer operation is not dependent on the phase-locked loops (PLLs) in the clock manager. This independence allows recovery from software that inadvertently programs the PLLs in the clock manager incorrectly.

Related Information

[Clock Manager](#) on page 3-1

For more information, refer to the *Clock Manager* chapter.

Watchdog Timer Resets

Watchdog timers are reset by a cold or warm reset from the reset manager, and are disabled when exiting reset. †

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to the *Reset Manager* chapter.

Taking the Watchdog Timer Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

FPGA Interface

The watchdog timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Platform Designer (Standard)

Watchdog Timer Programming Model

Setting the Timeout Period Values

The watchdog timers have a dual timeout period. The counter uses the initial start timeout period value the first the timer is started. All subsequent restarts use the restart timeout period. The valid values are $2^{(16+i)} - 1$ clock cycles, where i is an integer from 0 to 15. To set the programmable timeout periods, perform the following actions in no specific order:

Note: Set the timeout values before enabling the timer.

- To set the initial start timeout period, write i to the timeout period for the initialization field (`top_init`) of the watchdog timeout range register (`wdt_torr`).
- To set the restart timeout period, write i to the timeout period field (`top`) of the `wdt_torr` register

Selecting the Output Response Mode

The watchdog timers have two output response modes. To select the desired mode, perform one of the following actions:

- To generate a system reset request when a timeout occurs, write 0 to the output response mode bit (`rmod`) of the watchdog timer control register (`wdt_cr`).
- To generate an interrupt and restart the timer when a timeout occurs, write 1 to the `rmod` field of the `wdt_cr` register.

If a restart occurs at the same time the watchdog counter reaches zero, a system reset is not generated. †

Related Information

[Watchdog Timer Counter](#) on page 25-2

Enabling and Initially Starting a Watchdog Timer

To enable and start a watchdog timer, write the value 1 to the watchdog timer enable bit (`wdt_en`) of the `wdt_cr` register.

Reloading a Watchdog Counter

To reload a watchdog counter, write the value 0x76 to the counter restart register (`wdt_crr`). This unique 8-bit value is used as a safety feature to prevent accidental restarts.

Pausing a Watchdog Timer

Pausing the watchdog timers is controlled by the L4 watchdog debug register (`wddbq`) in the system manager.

Related Information

[Features of the System Manager](#) on page 6-1

For more information, refer to the *System Manager* chapter.

Disabling and Stopping a Watchdog Timer

The watchdog timers are disabled and stopped by resetting them from the reset manager.

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to the *Reset Manager* chapter.

Watchdog Timer State Machine

The following figure illustrates the behavior of the watchdog timer, including the behavior of both output response modes. Once initialized, the counter decrements at every clock cycle. The state machine remains in the Decrement Counter state until the counter reaches zero, or the watchdog timer is restarted. If software reads the interrupt clear register (`wdt_eoi`), or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to Decrement Counter.

Figure 25-2: Watchdog Timer State Machine

If the counter reaches zero, the state changes based on the value of the output response mode setting defined in the `rmod` bit of the `wdt_cr` register. If the `rmod` bit of the `wdt_cr` register is 0, the output response mode is to generate a system reset request. In this case, the state changes to Assert System Reset Request. In response, the reset manager resets and disables the watchdog timer, and gives software the opportunity to reinitialize the timer.

If the `rmod` bit of the `wdt_cr` register is 1, the output response mode is to generate an interrupt. In this case, the state changes to Assert Interrupt and Load Counter with Restart Timeout Value. An interrupt to the processor is generated, and the watchdog counter is reloaded with the restart timeout value. The state then changes to the second Decrement Counter state, and the counter resumes decrementing. If software reads the `wdt_eoi` register, or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to the first Decrement Counter state. If the counter again reaches zero, the state changes to Assert System Reset Request. In response, the reset manager resets the watchdog timer, and gives software the opportunity to reinitialize the timer.

Watchdog Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- L4 Watchdog Module 0
- L4 Watchdog Module 1

The hard processor system (HPS) provides two controller area network (CAN) controllers for serial communication with the Cortex-A9 microprocessor unit (MPU) subsystem host processor and the direct memory access (DMA) controller using the CAN protocol. The CAN controllers are instances of the Bosch D_CAN controller and compliant with ISO 11898-1.

Features of the CAN Controller

The CAN controllers offer the following features:

- Compliant with CAN Protocol Specification 2.0 parts A and B, available from the Bosch website.
- Programmable communication rate up to 1 Mbps
- Holds up to 128 messages
- Error correction code (ECC)
- 11-bit standard and 29-bit extended identifiers
- Programmable loopback mode
- External direct memory access (DMA) controller for large data transfers
- Automatic retransmission

CAN Controller Block Diagram and System Integration

Figure 26-1: CAN Controller Block Diagram

The CAN controller consists of the following modules and interfaces:

- CAN core
 - Connects to the CAN bus interface
 - Handles all ISO 11898-1 protocol functions
- Message handler
 - State machine that controls the data transfer between the message RAM and CAN core.
 - Handles acceptance filtering and the interrupt generation
- Message RAM
 - Storage for up to 128 messages objects
 - Single bit error correction and double bit error detection
- Message RAM interface
 - Two separate interfaces, $IF1$ and $IF2$
- Register block
 - Control and status registers (CSR) for module setup and indirect message object access.
 - All host processor accesses to the message RAM are relayed through the message RAM interface.
- Level 4 (L4) slave interface for CSR accesses

Functional Description of the CAN Controller

The CAN controllers perform communication according to the CAN protocol version 2.0 parts A and B. All communication on the CAN bus is through message objects. The CAN controller stores message objects in its internal message RAM. The host processor cannot access the message RAM directly, instead the $IF1$ and $IF2$ message interface register sets provide the host processor access to the messages. Messages are passed between the message RAM and the CAN core by the message handler. The message handler is also responsible for message level responsibilities such as acceptance filtering, interrupt generation, and transmission request generation.

Message Object

The message RAM can store up to 128 message objects. To avoid conflicts between host processor accesses to the message RAM and CAN message reception and transmission, the host processor does not access the message objects directly. Accesses are handled through the $IF1$ and $IF2$ message interface registers.

The following table shows the structure of a message object, where the first row contains the message object control flags, the second row contains the message object masks, and the third row is the CAN message.

Table 26-1: Message Object Structure

Msg Val				NewDat	MsgLst	IntPnd		TxIE	RxIE	RmtEn	TxRqst	EoB
UMask	Msk [28:0]	MXtd	MDir									
	ID [28:0]	Xtd	Dir	DLC [3:0]	Data 0 [7:0]	Data 1 [7:0]	Data 2 [7:0]	Data 3 [7:0]	Data 4 [7:0]	Data 5 [7:0]	Data 6 [7:0]	Data 7 [7:0]

Message Object Control Flags

Message Valid (MsgVal) on page 26-4

New Data (NewDat) on page 26-4

Message Lost (MsgLst) on page 26-4

Interrupt Pending (IntPnd) on page 26-4

Transmit Interrupt Enable (TxIE) on page 26-5

Receive Interrupt Enable (RxIE) on page 26-5

Remote Enable (RmtEn) on page 26-5

Transmit Request (TxRqst) on page 26-5

End of Block (EoB) on page 26-5

Message Valid (MsgVal)

- 0= The message object is ignored by the message handler
- 1= The message object is configured and should be considered by the message handler

The host processor must set the `MsgVal` bit of all unused message objects to 0 before it resets the initialization bit (`Init`) of the CAN control register (`CCTRL`) to initialize the CAN controller. `MsgVal` must also be set to 0 when the message object is no longer in use.

The `MsgVal` field is directly readable from the message valid registers (`MOVALA`, `MOVALB`, `MOVALC`, `MOVALD`, and `MOVALX`). However, to write to the `MsgVal` field for a specific message object, the host processor must write to the message interface registers.

New Data (NewDat)

- 0= No new data has been written into the data portion of this message object by the message handler since last time this flag was cleared by the host processor.
- 1= The message handler or the host processor has written new data to the data portion of this message object.

The `NewDat` field is directly readable from the new data registers (`MONDA`, `MONDB`, `MONDC`, `MONDD`, and `MONDX`). However, to write to the `NewDat` field for a specific message object, the host processor must write to the message interface registers.

Message Lost (MsgLst)

- 0= No message lost since last time this bit is was last reset by the host processor
- 1= The message handler stored a new message into this object when the `NewDat` bit was still set, indicating the host processor has lost a message.

`MsgLst` is valid only in message objects with the message direction bit (`Dir`) set to receive.

Interrupt Pending (IntPnd)

- 0= This message object is not the source of an interrupt.
- 1= This message object is the source of an interrupt. The interrupt identifier field in the CAN interrupt register (`CIR`) points to this message object if there is no other interrupt source with higher priority.

The `IntPnd` field is directly readable from the interrupt pending registers (`MOIPA`, `MOIPB`, `MOIPC`, `MOIPD`, and `MOIPX`). However, to write to the `IntPnd` field for a specific message object, the host processor must write to the message interface registers.

Transmit Interrupt Enable (TxIE)

- 0= TxIE is disabled. `IntPnd` is left unchanged after the successful transmission of a frame.
- 1= TxIE is enabled. `IntPnd` is set after a successful transmission of a frame.

Receive Interrupt Enable (RxIE)

- 0= RxIE is disabled. `IntPnd` is left unchanged after a successful reception of a frame.
- 1= RxIE is enabled. `IntPnd` is set after a successful reception of a frame.

Remote Enable (RmtEn)

- 0= RmtEn is disabled. At the reception of a remote frame, `TxRqst` is left unchanged.
- 1= RmtEn is enabled. At the reception of a remote frame, `TxRqst` is set.

Transmit Request (TxRqst)

- 0= This message object is not waiting for transmission.
- 1= The transmission of this message object is requested and is not complete.

The `TxRqst` field is directly readable from the transmission request registers (`MOTRA`, `MOTRB`, `MOTRC`, `MOTRD`, and `MOTRX`). However, to write to the `TxRqst` field for a specific message object, the host processor must write to the message interface registers.

End of Block (EOB)

- 0= Message object belongs to a FIFO buffer block and is not the last message object of that FIFO buffer block.
- 1= Single message object or last message object of a FIFO buffer block.

This bit is used to concatenate two or more message objects (up to 128) to build a FIFO buffer. For single message objects (not belonging to a FIFO buffer), this bit must always be set to 1.

Message Object Mask Bits

The message object mask bits, together with the arbitration bits, are used for acceptance filtering of incoming messages.

[Use Acceptance Mask \(UMask\)](#) on page 26-6

[Identifier Mask \(Msk\[28:0\]\)](#) on page 26-6

[Extended Identifier Mask \(MXtd\)](#) on page 26-6

[Mask Message Direction \(MDir\)](#) on page 26-6

Use Acceptance Mask (UMask)

- 0= Ignore mask. $MSK[28:0]$, $MXtd$, and $MDir$ have no effect on acceptance filtering. For an incoming message to be accepted, all the following conditions must be met:
 - The received message is a data frame with message direction set to 0 (receive) or is a remote frame with message direction set to 1 (transmit).
 - The received message identifier matches the message identifier ($ID[28:0]$) of the message object.
 - The received identifier extension bit matches the identifier extension bit (Xtd) of the message object.
- 1= Use mask ($MSK[28:0]$, $MXtd$, and $MDir$) for acceptance filtering if the respective mask bits are set up for acceptance filtering. For an incoming message to be accepted, all the following conditions must be met:
 - The received message is a data frame with message direction set to 0 (receive) or is a remote frame with message direction set to 1 (transmit) with the $MDir$ mask bit enabled.
 - The received message identifier matches the message identifier ($ID[28:0]$) of the message object with the $MSK[28:0]$ mask bits enabled
 - The received identifier extension bit matches the identifier extension bit (Xtd) of the message object, with the $MXtd$ mask bit enabled.

Note: If the $UMask$ bit is set to 1, the message object's mask bits have to be programmed during the initialization of the message object before $MSGVal$ is set to 1.

Identifier Mask ($MSK[28:0]$)

The identifier mask filters the corresponding bits in $ID[28:0]$.

- 0= The corresponding identifier bit has no effect on the acceptance filter.
- 1= The corresponding identifier bit is used for acceptance filtering.

Extended Identifier Mask ($MXtd$)

- 0= The extended frame identifier bit (Xtd) has no effect on the acceptance filtering
- 1= The extended frame identifier bit (Xtd) is used for acceptance filtering

When 11-bit (standard) identifiers are used for a message object, the identifiers of received data frames are written to bits $ID28$ to $ID18$. For acceptance filtering, only these bits, together with mask bits $MSK28$ to $MSK18$, are used.

Mask Message Direction ($MDir$)

- 0= The message direction bit (Dir) has no effect on the acceptance filtering.
- 1= The message direction bit (Dir) is used for acceptance filtering.

Important: Altera recommends always setting $MDir$ to 1. Ignoring the message direction bit is an advanced technique that must be handled with great care.

CAN Message Bits

The arbitration fields $ID28-0$, Xtd , and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask fields $MSK28-0$, $MXtd$, and $MDir$) for acceptance filtering of incoming messages. A received message is stored to the valid message object with matching identifier when the direction is set to receive a data frame or transmit a remote frame. Extended frames can be stored only in message objects with Xtd is set to 1, standard frames in message objects with Xtd is set to 0. If a received message (data frame or remote frame) matches more than one valid message object, it is stored to the object with the lowest message number.

[Message Identifier \(ID\[28:0\]\)](#) on page 26-7

[Extended Frame Identifier \(Xtd\)](#) on page 26-7

[Message Direction \(Dir\)](#) on page 26-7

[Data Length Code \(DLC\[3:0\]\)](#) on page 26-7

[Data Bytes 0-7 \(Data 0\[7:0\] - Data 7\[7:0\]\)](#) on page 26-7

Message Identifier (ID[28:0])

- ID28-ID0: 29-bit identifier (extended frame)
- ID28-ID18: 11-bit identifier (standard frame)

Extended Frame Identifier (xtd)

- 0= The 11-bit (standard) identifier is used for this message object.
- 1= The 29-bit (extended) identifier is used for this message object.

Message Direction (dir)

- 0= receive direction. When TxRqst is set to 1, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, that message is stored in this message object.
- 1= transmit direction. When TxRqst is set to 1, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set to 1 (if RmtEn = 1).

Data Length Code (DLC[3:0])

DLC specifies the number of data bytes in the data frame. The maximum number is eight.

The data length code (DLC) of a message object must be defined the same as in all the corresponding objects with the same identifier in all CAN devices. When the message handler stores a data frame, it sets the DLC field to the value provided in the received message.

Data Bytes 0-7 (Data 0[7:0] - Data 7[7:0])

The data bytes in a CAN data frame.

Message Interface Registers

There are two sets of message interface registers, IF1 and IF2, that provide a means for a host processor or DMA controller to access any message object indirectly. Message objects are transferred between the message RAM and the message buffer registers as a single, atomic operation maintaining data consistency across the message.

Table 26-2: Message Interface Register Set

This table lists the structure of each message interface register set, where *x* represents either set 1 or set 2.

Register Type	Register	Name	Description
Command	IF _x CMR	IF _x command register	Specifies the transfer direction and selects the portions of the message object to transfer

Register Type	Register	Name	Description
Message buffer	IFxMSK	IFx mask register	Provides access to the <code>MSK</code> , <code>MDir</code> , and <code>MXtd</code> mask fields of the message object
	IFxARB	IFx arbitration register	Provides access to the <code>ID</code> , <code>Dir</code> , <code>Xtd</code> , and <code>MsgVal</code> arbitration fields of the message object
	IFxMCTR	IFx message control register	Provides access to the <code>DLC</code> , <code>EoB</code> , <code>TxRqst</code> , <code>RmtEn</code> , <code>RxIE</code> , <code>TxIE</code> , <code>UMask</code> , <code>IntPnd</code> , <code>MsgLst</code> , and <code>NewDat</code> fields of the message object
	IFxDA	IFx data A register	Provides access to data bytes 0-3 of the message object
	IFxDB	IFx data B register	Provides access to data bytes 4-7 of the message object

DMA Mode

The CAN controller can issue DMA controller requests to transfer data between one or both of the message interface registers and system memory. The CAN controller has two DMA request interfaces, called `can_if1dma` and `can_if2dma`. The CAN peripheral request interfaces are shared with the FPGA DMA peripheral request interfaces. To use the DMA peripheral request interface, the host processor must access the CAN control register (`CCTRL`) in the protocol group (`protogrp`). The peripheral request interface is selected through the system manager.

To activate the DMA support feature and initiate a transfer, write a 1 to the `DMAActive` bit in the appropriate IF command register (`IFxCMR`) in the message interface group (`msgifgrp`). After the message object transfer is completed, the CAN controller issues a DMA peripheral request to perform the next message object transfer. The request remains active until the first read or write to the message interface register.

Related Information

- [System Manager](#) on page 6-1
- [DMA Controller](#) on page 17-1

Automatic Retransmission

The CAN controller provides a means for automatic retransmission of frames that have lost arbitration or have errors during transmission. Retransmission happens automatically without user intervention or notification. Normal confirmation is given when the transmission is successfully complete.

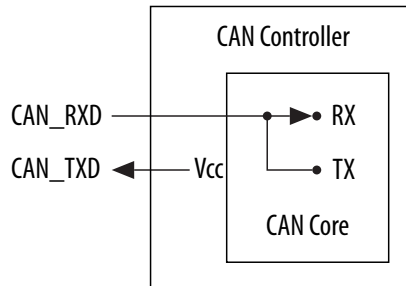

Test Mode

To enable test mode, set the test mode enable bit (`Test`) in the `CCTRL` register to 1. This action activates write access to the CAN test register (`CTR`).

Silent Mode

The CAN controller is set in the silent mode by programming the silent mode (`SiLent`) bit in the test register (`CTR`) to 1. In silent mode, the CAN controller is able to receive valid data frames and valid remote frames, but it holds the `CAN_TXD` pin high, sending no data to the CAN bus. The silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (acknowledge bits, error frames). In ISO 11898-1, the silent mode is called the *bus monitoring mode*.

Figure 26-2: CAN Core in Silent Mode

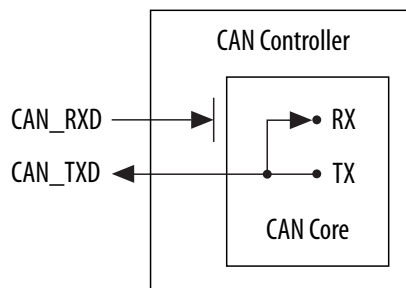

Loopback Mode

The CAN controller is set in loopback mode by programming the loopback mode (`LBaCk`) bit in the test register (`CTR`) to 1. In loopback mode, the CAN controller treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) to a receive buffer.

To be independent from external stimulation, the CAN controller ignores acknowledge errors in loopback mode. In this mode, the CAN controller provides internal feedback from its transmit (`TX`) output to its receive (`RX`) input. The actual value of the input pin is disregarded by the CAN controller.

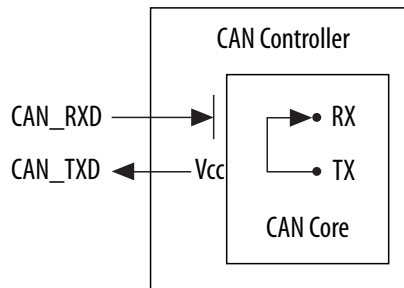

Figure 26-3: CAN Core in Loopback Mode

Combined Mode

The CAN controller is set in combined loopback and silent mode by programming the silent mode (`SiLent`) and loopback mode (`LBaCk`) bits in the test register (`CTR`) to 1. Combined mode can be used for testing the CAN hardware without affecting other devices connected to the CAN bus. In this mode, the `CAN_RXD` pin is disconnected from the CAN core and the `CAN_TXD` pin is held high.

Figure 26-4: CAN Core in Combined Mode

L4 Slave Interface

The host processor accesses data, control, and status information of the CAN controller through the L4 slave interface. The slave interface supports 32-bit accesses only.

Note: This interface does not support error responses.

Clocks

The CAN controller operates on the `l4_sp_clk` and `can_clk` clock inputs. The `l4_sp_clk` clock is used by the L4 slave interface and the `can_clk` is used to operate the CAN core.

The `can_clk` clock must be programmed to be at least eight times the CAN bus interface speed. For example, for a CAN bus interface operating at a 1 Mbps baud rate, the `can_clk` clock must be set to at least 8 MHz. The `l4_sp_clk` clock can operate at a clock frequency that is equal to or greater than the `can_clk` frequency.

Related Information

[Clock Manager](#) on page 3-1

For more information about the `l4_sp_clk` and `can_clk` clocks, refer to the *Clock Manager* chapter.

Software Reset

Software initialization is done by setting the `init` bit in the CAN control register (`CCTRL`) in the protocol group (`protogrpf`) in the CAN controller register map. This bit is set through the CAN protocol when a bus off condition occurs on the CAN link. The bit is also set through the hardware reset input described in Hardware Reset.

Due to the synchronization mechanism between the two clock domains, there might be a delay until the value written to the `init` bit can be read back. To assure that the previous value written has been accepted, read the `init` bit before setting it to a new value.

The bus off recovery sequence cannot be shortened by setting or resetting the `init` bit. For more information about bus off, refer to the CAN Protocol Specification 2.0 parts A and B, available from the Bosch website.

Related Information

- [Hardware Reset](#) on page 26-11
- [Bosch Semiconductor](#)

Hardware Reset

Each CAN controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset. The reset signal is synchronized to both clock domains and applied to the appropriate logic within the CAN controllers.

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to the *Reset Manager* chapter.

Taking the CAN Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Each CAN controller generates two interrupt signals. One signal indicates error and status interrupts and the other signal indicates message object interrupts. Both interrupt signals connect to the global interrupt controller (GIC). Interrupts are enabled in the CAN control register (CTRL) in the protocol group (protogrp). The CAN interrupt register (CIR) in the protocol group (protogrp) indicates the highest priority interrupt that is pending.

Error Interrupts

The following error conditions generate interrupts:

- Bus off—when the transmit error count is equal to or greater than 256, the bus off (BOFF) bit in the CAN status register (CSTS) in the protocol group (protogrp) is set to 1.
- Error warning—when either the transmit error counter or the receive error counters reaches 96, the error warning status (EWARN) bit in the CAN status register (CSTS) in the protocol group (protogrp) is set to 1.

Status Interrupts

The following status conditions generate interrupts:

- Receive OK—when the CAN controller receives a message successfully, the RXOK bit in the CAN status register (CSTS) in the protocol group (protogrp) is set to 1.
- Transmit OK—when the CAN controller transmits a message successfully, the TXOK bit in the CAN status register (CSTS) in the protocol group (protogrp) is set to 1.
- Last error code—when a message is received or transmitted with an error, the LEC bits in the CAN status register (CSTS) in the protocol group (protogrp) are set according to the error type.

Message Object Interrupts

The IntPnd bits from the message objects can generate interrupts when the corresponding message object TXIE bit or RXIE bit is set to 1. The table lists the location of message object interrupt information in the interrupt pending registers. The interrupt pending registers are located in the message handler group (msghandgrp).

Table 26-3: Message Object Interrupt Registers

Register	Title	Message Objects
MOIPA	Interrupt pending A register	1 to 32
MOIPB	Interrupt pending B register	33 to 64
MOIPC	Interrupt pending C register	65 to 96
MOIPD	Interrupt pending D register	97 to 128

The MOIPX register allows software to quickly detect which message object group has a pending interrupt.

CAN Controller Programming Model

Software Initialization

The software initialization is started by setting the `Init` bit in the CAN control register (`CCTRL`) to 1. While the `Init` bit is 1, messages are not transferred to or from the CAN bus, and the `CAN_TXD` CAN bus output is held in the high state. Setting the `Init` bit does not change any configuration registers.

To initialize the CAN controller, the host processor must program the CAN bit timing (`CBT`) register and message objects that will be used for CAN communication. If a message object is not needed, it is sufficient to set the `MsgVal` bit of the message object to not valid (0), which is the default after RAM initialization. You must set up the entire message object before setting `MsgVal` bit to valid (1). The message objects are set up through either message interface register set.

Access to the CAN bit timing (`CBT`) register is only enabled when the configuration change enable (`CCE`) and `Init` bits in the CAN control register (`CCTRL`) are both set to 1.

Setting the `Init` bit to 0 finishes the software initialization. The CAN core synchronizes itself to the data transfer on the CAN bus by waiting for the bus to reach an idle state before it can take part in bus activities and message transfers.

The initialization of the message objects is independent of the CAN controller initialization and can be done anytime, but the message objects should all be configured to particular identifiers or set to not valid before message transferring begins.

On power up, the message RAM has to be initialized. To initialize RAM, set the `Init` bit to 1, then set the `RAMInit` bit in the CAN function register (`CFR`) in the protocol group (`protogrp`) to 1. The `RAMInit` bit returns to 0 when RAM initialization completes. During RAM initialization, all message objects are cleared to zero and the RAM ECC bits are initialized. Access to RAM is not allowed prior to or during RAM initialization.

CAN Message Transfer

Once the CAN controller is initialized, the CAN controller synchronizes itself to the CAN bus and starts transferring messages.

Received messages are stored to their appropriate message objects, if they pass the message handler's acceptance filtering. The entire message, including all arbitration bits, `Xtd`, `Dir`, `DLC`, eight data bytes, the mask and control bits `UMask`, `MXtd`, `MDir`, `EoB`, `MsgLst`, `RxIE`, `TxIE`, and `RmtEn`, is stored in the message object. Masked arbitration bits might change in the message object when a received message is stored.

The host processor may read or update each message at any time using the message interface registers. The message handler guarantees data consistency when the host processor accesses the message object at the same time the message is being transferred to or from RAM.

Messages to be transmitted are updated by the host processor. If a permanent message object (arbitration and control bits set up during configuration are unchanged for multiple CAN transfers) exists for the message, only the data bytes need to be updated. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time they are transmitted, according to their internal priority. The message object numbers are 1 to 128, with 1 being the highest internal priority and 128 the lowest priority. Messages may be updated or set to invalid (`MsgVal=0`) at anytime, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started.

Depending on the configuration on the message object, the transmission of a message may be requested automatically by the reception of a remote frame with a matching identifier. Remote frames are frames used to request a particular message on the CAN network.

Note: For ease in programming, Altera recommends using one `IF` message interface for all receive direction activity and the other `IF` message interface for all transmit direction activity.

Message Object Reconfiguration for Frame Reception

To configure a message object to receive data frames, set the `Dir` field to 0.

To configure a message object to receive remote frames, set the `Dir` field to 1, set `UMask` to 1, and set `RmtEn` to 0.

To avoid modifying an object while it is being transmitted, you must set `MsgVal` to 0 before changing any of the following configuration and control bits:

- `ID[28:0]`
- `Xtd`
- `DLC[3:0]`
- `RxIE`
- `TxIE`
- `RmtEn`
- `EoB`
- `UMask`
- `Msk[28:0]`
- `MXtd`
- `MDir`

The following fields of a message object can be changed without clearing `MsgVal`:

- `Data0[7:0]` to `Data7[7:0]`
- `TxRqst`
- `NewDat`
- `MsgLst`
- `IntPnd`

Message Object Reconfiguration for Frame Transmission

To configure a message object to transmit data frames, set the `Dir` field to 1, and either set `UMask` to 0 or set `RmtEn` to 1.

Before changing any of the following configuration and control bits, you must set `MsgVal` to 0:

- `Dir`
- `RxIE`
- `TxIE`
- `RmtEn`
- `EoB`
- `UMask`
- `Msk[28:0]`
- `MXtd`
- `MDir`

The following fields of a message object can be changed without clearing `MsgVal`:

- `ID[28:0]`
- `Xtd`
- `DLC[3:0]`
- `Data0[7:0]` to `Data7[7:0]`
- `TxRqst`
- `NewDat`
- `MsgLst`
- `IntPnd`

CAN Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- CAN Controller Module 0
- CAN Controller Module 1

Related Information

Protocol Group Register Descriptions

These registers are related to the CAN protocol controller in the CAN Core. They control the operating modes and the configuration of the CAN bit timing and provide status information.

Offset: 0x0

CCTRL on page 26-18

Control Register

CSTS on page 26-21

Status Register

CERC on page 26-24

Error Counter Register

CBT on page 26-25

This register is only writable if bits CCTRL.CCE and CCTRL.Init are set. The CAN bit time may be programmed in the range of [4 .. 25] time quanta. The CAN time quantum may be programmed in the range of [1 .. 1024] CAN_CLK periods. For details see Application Note 001 "Configuration of Bit Timing". The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. TSeg1 is the sum of Prop_Seg and Phase_Seg1. TSeg2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [TSeg1 + TSeg2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

CIR on page 26-27

If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it. If IntID is different from 0x00 and CCTRL.MIL is set, the interrupt port CAN_INT_MO is active. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is reset. If CCTRL.ILE is set and CCTRL.MIL is reset the Message Object interrupts will be routed to interrupt port CAN_INT_STATUS. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is set or CCTRL.ILE is reset. The Message Object's interrupt priority decreases with increasing message number. A message interrupt is cleared by clearing the Message Object's IntPnd bit.

CTR on page 26-28

The Test Mode is entered by setting bit CCTRL.Test to one. In Test Mode the bits EXL, Tx1, Tx0, LBack and Silent in the Test Register are writable. Bit Rx monitors the state of pin CAN_RXD and therefore is only readable. All Test Register functions are disabled when bit Test is reset to zero. Loop Back Mode and CAN_TXD Control Mode are hardware test modes, not to be used by application programs. Note: This register is only writable if bit CCTRL.Test is set.

CFR on page 26-29

The Function Register controls the features RAM_Initialisation and Power_Down also by application register. The CAN module can be prepared for Power_Down by setting the port CAN_CLKSTOP_REQ to one or writing to CFR.ClkStReq a one. The power down state is left by setting port CAN_CLKSTOP_REQ to zero or writing to CFR.ClkStReq a zero, acknowledged by CAN_CLKSTOP_ACK is going to zero as well as CFR.ClkStAck. The CCTRL.Init bit is left one and has to be written by the application to re-enable CAN transfers. Note: It's recommended to use either the ports CAN_CLKSTOP_REQ and CAN_CLKSTOP_ACK or the CCTRL.ClkStReq and CFR.ClkStAck. The application CFR.ClkStReq shows also the actual status of the port CAN_CLKSTOP_REQ.

Bit	Name	Description	Access	Reset						
0	Init	<p>Initialization Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to CCTRL.Init can be read back. Therefore the programmer has to assure that the previous value written to CCTRL.Init has been accepted by reading CCTRL.Init before setting CCTRL.Init to a new value.</p> <p>Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or resetting CCTRL.Init. If the device goes Bus_Off, it will set CCTRL.Init of its own accord, stopping all bus activities. Once CCTRL.Init has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operations. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCTRL.Init, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the Status Register, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the proceeding of the us_Off recovery sequence.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Normal Operation.</td> </tr> <tr> <td>0x1</td> <td>Initialization is started.</td> </tr> </tbody> </table>	Value	Description	0x0	Normal Operation.	0x1	Initialization is started. CBT

This register is only writable if bits CCTRL.CCE and CCTRL.Init are set. The CAN bit time may be programmed in the range of [4 .. 25] time quanta. The CAN time quantum may be programmed in the range of [1 .. 1024] CAN_CLK periods. For details see Application Note 001 "Configuration of Bit Timing". The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. TSeg1 is the sum of Prop_Seg and Phase_Seg1. TSeg2 is Phase_Seg2. Therefore the length of the

bit time is (programmed values) [TSeg1 + TSeg2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

Bit	Name	Description	Access	Reset
5:0	BRP	The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are [0 .. 63]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.	RW	0x1

CIR

If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it. If IntID is different from 0x00 and CCTRL.MIL is set, the interrupt port CAN_INT_MO is active. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is reset. If CCTRL.ILE is set and CCTRL.MIL is reseted the Message Object interrupts will be routed to interrupt port CAN_INT_STATUS. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is set or CCTRL.ILE is reset. The Message Object's interrupt priority decreases with increasing message number. A message interrupt is cleared by clearing the Message Object's IntPnd bit.

CTR

The Test Mode is entered by setting bit CCTRL.Test to one. In Test Mode the bits EXL, Tx1, Tx0, LBack and Silent in the Test Register are writable. Bit Rx monitors the state of pin CAN_RXD and therefore is only readable. All Test Register functions are disabled when bit Test is reset to zero. Loop Back Mode and CAN_TXD Control Mode are hardware test modes, not to be used by application programs. Note: This register is only writable if bit CCTRL.Test is set.

CFR

The Function Register controls the features RAM_Initialisation and Power_Down also by application register. The CAN module can be prepared for Power_Down by setting the port CAN_CLKSTOP_REQ to one or writing to CFR.ClkStReq a one. The power down state is left by setting port CAN_CLKSTOP_REQ to zero or writing to CFR.ClkStReq a zero, acknowledged by CAN_CLKSTOP_ACK is going to zero as well as CFR.ClkStAck. The CCTRL.Init bit is left one and has to be written by the application to re-enable CAN transfers. Note: It's recommended to use either the ports CAN_CLKSTOP_REQ and CAN_CLKSTOP_ACK or the CCTRL.ClkStReq and CFR.ClkStAck. The application CFR.ClkStReq shows also the actual status of the port CAN_CLKSTOP_REQ.

3	RAMinit	Request for automatic RAM Initialization Value Description 0x0 No automatic RAM Initialization is requested, if once a ram initialization is started a write of a zero will be ignored. The Bit is cleared by hardware, after RAM Initialization is completed. 0x1 Start automatic RAM Initialization. All message objects will be written with zeros and the parity bits will be set. The RAMInit Bit will return to zero after the RAM-Initialization process is completed. A RAM Initialization Request is only possible if CCTRL.Init is set. The duration of the automatic RAM Initialization is messagebuffer-size + 4 host_ clock cycles.	RW	0x0
1	ClkStReq	Clock Stop Request	RW	0x0
0	ClkStAck	Clock Stop Acknowledgement	RO	0x0

Message Handler Group Register Descriptions

These registers are related to the operation of the Message Handler. The Message Handler is a state machine that controls the data transfer between the single ported Message RAM and the CAN Core's Rx/Tx Shift Register. It also handles acceptance filtering and the interrupt setting as programmed in the Control and Configuration Registers.

Offset: 0x84

MOTRX on page 26-35

Reading this register allows the CPU to quickly detect if any of the transmission request bits in each of the MOTRA, MOTRB, MOTRC, and MOTRD Transmission Request Registers are set.

MOTRA on page 26-40

Transmission request bits for Message Objects 1 to 32. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRB on page 26-49

Transmission request bits for Message Objects 33 to 64. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRC on page 26-58

Transmission request bits for Message Objects 65 to 96. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRD on page 26-66

Transmission request bits for Message Objects 97 to 128. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MONDX on page 26-75

Reading this register allows the CPU to quickly detect if any of the new data bits in each of the MONDA, MONDB, MONDC, and MONDD New Data Registers are set.

MONDA on page 26-80

New data bits for Message Objects 1 to 32. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDB on page 26-91

New data bits for Message Objects 33 to 64. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDC on page 26-102

New data bits for Message Objects 65 to 96. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDD on page 26-114

New data bits for Message Objects 97 to 128. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MOIPX on page 26-125

Reading this register allows the CPU to quickly detect if any of the interrupt pending bits in each of the MOIPA, MOIPB, MOIPC, and MOIPD Interrupt Pending Registers are set.

MOIPA on page 26-131

Interrupt pending bits for Message Objects 1 to 32. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPB on page 26-140

Interrupt pending bits for Message Objects 33 to 64. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPC on page 26-148

Interrupt pending bits for Message Objects 65 to 96. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPD on page 26-157

Interrupt pending bits for Message Objects 97 to 128. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOVALX on page 26-166

Reading this register allows the CPU to quickly detect if any of the message valid bits in each of the MOVALA, MOVALB, MOVALC, and MOVALD Message Valid Registers are set.

MOVALA on page 26-172

Message valid bits for Message Objects 1 to 32. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALB on page 26-180

Message valid bits for Message Objects 33 to 64. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALC on page 26-189

Message valid bits for Message Objects 65 to 96. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALD on page 26-197

Message valid bits for Message Objects 97 to 128. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOTRX

Reading this register allows the CPU to quickly detect if any of the transmission request bits in each of the MOTRA, MOTRB, MOTRC, and MOTRD Transmission Request Registers are set.

MOTRA

Transmission request bits for Message Objects 1 to 32. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRB

Transmission request bits for Message Objects 33 to 64. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC0008C
can1	0xFFC01000	0xFFC0108C

Offset: 0x8C

Access: RO

MOTRC

Transmission request bits for Message Objects 65 to 96. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC00090
can1	0xFFC01000	0xFFC01090

Offset: 0x90

MOTRD

Transmission request bits for Message Objects 97 to 128. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC00094
can1	0xFFC01000	0xFFC01094

Offset: 0x94

MONDX

Reading this register allows the CPU to quickly detect if any of the new data bits in each of the MONDA, MONDB, MONDC, and MONDD New Data Registers are set.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC00098
can1	0xFFC01000	0xFFC01098

Offset: 0x98

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MONDA

New data bits for Message Objects 1 to 32. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC0009C
can1	0xFFC01000	0xFFC0109C

Offset: 0x9C

MONDB

New data bits for Message Objects 33 to 64. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

Module Instance	Base Address	Register Address

MONDC

New data bits for Message Objects 65 to 96. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000A4
can1	0xFFC01000	0xFFC010A4

MONDD

New data bits for Message Objects 97 to 128. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000A8
can1	0xFFC01000	0xFFC010A8

Offset: 0xA8

MOIPX

Reading this register allows the CPU to quickly detect if any of the interrupt pending bits in each of the MOIPA, MOIPB, MOIPC, and MOIPD Interrupt Pending Registers are set.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000AC
can1	0xFFC01000	0xFFC010AC

Offset: 0xAC

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MOIPA

Interrupt pending bits for Message Objects 1 to 32. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPB

Interrupt pending bits for Message Objects 33 to 64. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000B4
can1	0xFFC01000	0xFFC010B4

MOIPC

Interrupt pending bits for Message Objects 65 to 96. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000B8
can1	0xFFC01000	0xFFC010B8

MOIPD

Interrupt pending bits for Message Objects 97 to 128. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000BC
can1	0xFFC01000	0xFFC010BC

Offset: 0xBC

MOVALX

Reading this register allows the CPU to quickly detect if any of the message valid bits in each of the MOVALA, MOVALB, MOVALC, and MOVALD Message Valid Registers are set.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000C0
can1	0xFFC01000	0xFFC010C0

Offset: 0xC0

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MOVALA

Message valid bits for Message Objects 1 to 32. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC000C4
can1	0xFFC01000	0xFFC010C4

Offset: 0xC4

MOVALB

Message valid bits for Message Objects 33 to 64. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

0x1	The Message Object is configured and should be considered by the Message Handler.									

MOVALC

Message valid bits for Message Objects 65 to 96. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

Message Interface Group Register Descriptions

These registers provide indirect read and write access for the host CPU to the Message RAM. Buffers the data to be transferred to and from the RAM, avoiding conflicts between CPU accesses and CAN frame reception/transmission. The function of the two Interface Register sets is identical. The second interface register set is provided to serve application programming. Two groups of software drivers may be defined, each group is restricted to the use of one of the Interface Register sets. The software drivers of one group may interrupt software drivers of the other group, but not of the same group. In a simple example, there is one Read_Message task that uses IF1 to get received messages from the Message RAM and there is one Write_Message task that uses IF2 to write messages to be transmitted into the Message RAM. Both tasks may interrupt each other. Each set of Interface Registers consists of registers controlled by their own Command Registers. The Command Mask Register specifies the direction of the data transfer and which parts of a Message Object will be transferred. The Command Request Register is used to select a Message Object in the Message RAM as target or source for the transfer and to start the action specified in the Command Mask Register.

Offset: 0x100

IF1CMR on page 26-208

The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between the Interface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

IF1MSK on page 26-213

The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF1ARB on page 26-215

The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

IF1MCTR on page 26-216

The Interface 1 Message Control Register is one of two registers sets that define and provide status for CPU read and write accesses to the Message RAM. The IF1MCTR register displays message status and controls message interrupt enables and transfer configuration.

IF1DA on page 26-219

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF1DB on page 26-220

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF2CMR on page 26-221

The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between the Interface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

IF2MSK on page 26-225

The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF2ARB on page 26-227

The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

IF2MCTR on page 26-228

The Interface 2 Message Control Register is one of two registers sets that define and provide status for CPU read and write accesses to the Message RAM. The IF2MCTR register displays message status and controls message interrupt enables and transfer configuration.

IF2DA on page 26-231

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF2DB on page 26-232

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF1CMR

The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between the Interface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one

is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

IF1CMR Fields

Bit	Name	Description	Access	Reset
29	ClrAutoInc	Clear the AutoInc bit without starting a transfer Value Description 0x0 Has no effect to the other Bits of this Register. 0x1 Clear the AutoInc bit without starting a transfer, all other bits will be ignored.	RW	0x0

Bit	Name	Description	Access	Reset						
23	WR1RDO	Write / Read Transfer <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transfer data from the Message Object addressed by IFxCMR.MONum into the selected IFx Message Buffer Registers.</td> </tr> <tr> <td>0x1</td> <td>Transfer data from the selected IFx Message Buffer Registers to the Message Object addressed by IFxCMR.MONum.</td> </tr> </tbody> </table>	Value	Description	0x0	Transfer data from the Message Object addressed by IFxCMR.MONum into the selected IFx Message Buffer Registers.	0x1	Transfer data from the selected IFx Message Buffer Registers to the Message Object addressed by IFxCMR.MONum.	RW	0x0
Value	Description									
0x0	Transfer data from the Message Object addressed by IFxCMR.MONum into the selected IFx Message Buffer Registers.									
0x1	Transfer data from the selected IFx Message Buffer Registers to the Message Object addressed by IFxCMR.MONum.									
22	Mask	Write Direction: 0= Mask bits unchanged. 1= transfer Identifier Mask + MDir + MXtd to Message Object. Read Direction: 0= Mask bits unchanged. 1= transfer Identifier Mask + MDir + MXtd to IFxMSK Register.	RW	0x0						
21	Arb	Write Direction: 0= Arbitration bits unchanged. 1= transfer Identifier + Dir + Xtd + MsgVal to Message Object. Read Direction: 0= Arbitration bits unchanged. 1= transfer Identifier + Dir + Xtd + MsgVal to IFxARB Register.	RW	0x0						
20	Control	Write Direction: 0= Control Bits unchanged. 1= transfer Control Bits to Message Object. Note: If IFxCMR.TxRqst/NewDat bit is set, bits IFxMCTR.TxRqst and IFxMCTR.NewDat will be ignored. Read Direction: 0= Control Bits unchanged. 1= transfer Control Bits to IFxMCTR Register.	RW	0x0						
19	ClrIntPnd	Write Direction: Has no influence to Message Object at write transfer. Note: When writing to a Message Object, this bit is ignored and copying of IntPnd flag from IFx Control Register to Message RAM could only be controlled by IFxMTR.IntPnd bit. Read Direction: 0= IntPnd bit remains unchanged. 1= clear IntPnd bit in the Message Object.	RW	0x0						

Bit	Name	Description	Access	Reset						
18	TxRqstNewDat	Write Direction: 0= TxRqst and NewDat bit will be handled according IFxMCTR.NewDat bit and IFxMCTR.TxRqst bit. 1= set TxRqst and NewDat in Message Object to one Note: If a CAN transmission is requested by setting IFxCMR.TxRqst/NewDat, the TxRqst and NewDat bits in the Message Object will be set to one independently of the values in IFxMCTR. Read Direction: 0= NewDat bit remains unchanged. 1= clear NewDat bit in the Message Object. Note: A read access to a Message Object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IFxMCTR always reflect the status before resetting them.	RW	0x0						
17	DataA	Write Direction: 0= Data Bytes 0-3 unchanged. 1= transfer Data Bytes 0-3 to Message Object. Read Direction: 0= Data Bytes 0-3 unchanged. 1= transfer Data Bytes 0-3 to IFxDA.	RW	0x0						
16	DataB	Write Direction: 0= Data Bytes 4-7 unchanged. 1= transfer Data Bytes 4-7 to Message Object. Read Direction: 0= Data Bytes 4-7 unchanged. 1= transfer Data Bytes 4-7 to IFxDB. Note: The speed of the message transfer does not depend on how many bytes are transferred.	RW	0x0						
15	Busy	<p>Busy Flag</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Set to zero when read/write action has finished.</td> </tr> <tr> <td>0x1</td> <td>Set to one when writing to the IFxCMR.MONum. While bit is one, IFx Register Set is write protected.</td> </tr> </tbody> </table>	Value	Description	0x0	Set to zero when read/write action has finished.	0x1	Set to one when writing to the IFxCMR.MONum. While bit is one, IFx Register Set is write protected.	RO	0x0
Value	Description									
0x0	Set to zero when read/write action has finished.									
0x1	Set to one when writing to the IFxCMR.MONum. While bit is one, IFx Register Set is write protected.									

Bit	Name	Description	Access	Reset						
14	DMAactive	<p>Activation of DMA feature for subsequent internal IFx Register Set</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>DMA line leaves passive, independent of IFx activities.</td> </tr> <tr> <td>0x1</td> <td>By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.</td> </tr> </tbody> </table>	Value	Description	0x0	DMA line leaves passive, independent of IFx activities.	0x1	By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.	RW	0x0
Value	Description									
0x0	DMA line leaves passive, independent of IFx activities.									
0x1	By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.									

Bit	Name	Description	Access	Reset						
13	AutoInc	<p>Automatic Increment of Message Object Number The behavior of the Message Object Number increment depends on the Transfer Direction, IFxCMR.WR1RD0. * Read: The first transfer will be initiated (Busy Bit will set) at write of IFxCMR.MONum. The Message Object Number will be incremented and the next Message Object will be transferred from Message Object RAM to Interface Registers after a read access of Data-Byte 7. * Write: The first as well as each other transfer will be started after write access to Data- Byte7. The Message Object Number will be incremented after successful transfer from the Interface Registers to the Message Object RAM. Always after successful transfer the Busy Bit will be reset. In combination with DMAactive the port CAN_IFxDMA is set, too. Note: If the direction is configured as Read a write access to Data-Byte 7 will not start any transfer, as well as if the direction is configured as Write a read access to Data-Byte 7 will not start any transfer. At transfer direction Read each read of Data-Byte 7 will start a transfer until IFxCMR.AutoInc is reset. To aware of resetting a NewDat bit of the following message object, the application has to reset IFxCMR.AutoInc before reading the Data-Byte 7 of the last message object which will be read.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>AutoIncrement of Message Object Number disabled.</td> </tr> <tr> <td>0x1</td> <td>AutoIncrement of Message Object Number enabled.</td> </tr> </tbody> </table>	Value	Description	0x0	AutoIncrement of Message Object Number disabled.	0x1	AutoIncrement of Message Object Number enabled.	RW	0x0
Value	Description									
0x0	AutoIncrement of Message Object Number disabled.									
0x1	AutoIncrement of Message Object Number enabled.									
7:0	MONum	<p>0x01-0x80 Valid Message Number, the Message Object in the Message RAM is selected for data transfer (up to 128 MsgObj). 0x00 Not a valid Message Number, interpreted as 0x80. 0x81-0xFF Not a valid Message Number, interpreted as 0x01-0x7F. Note: When an invalid Message Number is written to IFxCMR.MONum which is higher than the last Message Object number, a modulo addressing will occur. When e.g. accessing Message Object 33 in a CAN module with 32 Message Objects only, the Message Object 1 will be accessed instead.</p>	RW	0x1						

IF1MSK

The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF2CMR

The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between the Interface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC00120
can1	0xFFC01000	0xFFC01120

Offset: 0x120

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.</td> </tr> </tbody> </table>	Value	Description	0x0	DMA line leaves passive, independent of IFx activities.	0x1	By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.	RW	0x0
Value	Description									
0x0	DMA line leaves passive, independent of IFx activities.									
0x1	By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.									

Bit	Name	Description	Access	Reset						
13	AutoInc	<p>Automatic Increment of Message Object Number The behavior of the Message Object Number increment depends on the Transfer Direction, IFxCMR.WR1RD0. * Read: The first transfer will be initiated (Busy Bit will set) at write of IFxCMR.MONum. The Message Object Number will be incremented and the next Message Object will be transferred from Message Object RAM to Interface Registers after a read access of Data-Byte 7. * Write: The first as well as each other transfer will be started after write access to Data- Byte7. The Message Object Number will be incremented after successful transfer from the Interface Registers to the Message Object RAM. Always after successful transfer the Busy Bit will be reset. In combination with DMAactive the port CAN_IFxDMA is set, too. Note: If the direction is configured as Read a write access to Data-Byte 7 will not start any transfer, as well as if the direction is configured as Write a read access to Data-Byte 7 will not start any transfer. At transfer direction Read each read of Data-Byte 7 will start a transfer until IFxCMR.AutoInc is reset. To aware of resetting a NewDat bit of the following message object, the application has to reset IFxCMR.AutoInc before reading the Data-Byte 7 of the last message object which will be read.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>AutoIncrement of Message Object Number disabled.</td> </tr> <tr> <td>0x1</td> <td>AutoIncrement of Message Object Number enabled.</td> </tr> </tbody> </table>	Value	Description	0x0	AutoIncrement of Message Object Number disabled.	0x1	AutoIncrement of Message Object Number enabled.	RW	0x0
Value	Description									
0x0	AutoIncrement of Message Object Number disabled.									
0x1	AutoIncrement of Message Object Number enabled.									
7:0	MONum	<p>0x01-0x80 Valid Message Number, the Message Object in the Message RAM is selected for data transfer (up to 128 MsgObj). 0x00 Not a valid Message Number, interpreted as 0x80. 0x81-0xFF Not a valid Message Number, interpreted as 0x01-0x7F. Note: When an invalid Message Number is written to IFxCMR.MONum which is higher than the last Message Object number, a modulo addressing will occur. When e.g. accessing Message Object 33 in a CAN module with 32 Message Objects only, the Message Object 1 will be accessed instead.</p>	RW	0x1						

IF2MSK

The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF2ARB

The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

CAN Controller Revision History

Table 26-4: Can Controller Revision History

Document Version	Changes
2015.11.02	Updated "CAN Message Transfer" section.
2015.05.04	Maintenance release.
2014.12.15	<ul style="list-style-type: none"> Maintenance release. Added <i>Taking the CAN Controller Out of Reset</i> section.
2014.06.30	Add address map and register definitions
2014.02.28	Maintenance release
2013.12.30	Minor formatting updates
1.2	<ul style="list-style-type: none"> Minor updates. Expanded reset section. Expanded interrupts section.

Document Version	Changes
1.1	Added block diagram and system integration, functional description, programming model, and address map and register definitions sections.
1.0	Initial release.

Introduction to the HPS Component 27

Send Feedback

The hard processor system (HPS) component is a wrapper that interfaces logic in the user design to the HPS hard logic, simulation models, BFMs, and software handoff files. It instantiates the HPS hard logic in the user design; and enables other soft components to interface with the HPS hard logic. The HPS component itself has a small footprint in the FPGA fabric, because its only purpose is to enable soft logic to connect to the extensive hard logic in the HPS. You can connect soft logic to the HPS.

After the soft logic is connected to the HPS, Platform Designer (Standard) ensures the following features:

- Interoperability by adapting Avalon Memory-Mapped (Avalon-MM) interfaces to AXI
- Handle data width mismatches
- Clock domain transfer crossing

This allows you to integrate IP from Intel, 3rd party IP cores, and custom IP cores to the HPS without having to create integration logic.

For a description of the HPS and its integration into the system on a chip (SoC), refer to the *Cyclone V Device Datasheet*.

For a description of the HPS system architecture and features, refer to the "Introduction to the Hard Processor" and the CoreSight Debug and Trace chapters in volume 3 of the *Cyclone V Device Handbook*.

For more information about instantiating the HPS component, refer to the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about the HPS component interfaces, refer to the *HPS Component Interfaces* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about simulating the HPS component, refer to the *Simulating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

Interconnect

The interconnect consists of the L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The L3 interconnect is a partially-connected switch fabric.

Related Information

[System Interconnect](#) on page 8-1

HPS-to-FPGA Interfaces

The HPS-to-FPGA interfaces provide a variety of communication channels between the HPS and the FPGA fabric. The HPS is highly integrated with the FPGA fabric, resulting in thousands of connecting signals. Some of the HPS-to-FPGA interfaces include:

- FPGA-to-HPS port
- HPS-to-FPGA port
- Lightweight HPS-to-FPGA port
- FPGA-to-SDRAM interface

Related Information

You instantiate the hard processor system (HPS) component in Platform Designer (Standard). The HPS is available in the Platform Designer (Standard) IP catalog under **Processor and Peripherals > Hard Processor Systems**. This chapter describes the parameters available in the HPS component parameter editor, which opens when you add or edit an HPS component.

Related Information

General Interfaces

When enabled, the interfaces described in the following table become visible in the HPS component.

Table 28-1: General Parameters

Parameter Name	Parameter Description	Interface Name
Enable MPU standby and event signals	Enables interfaces that perform the following functions: <ul style="list-style-type: none"> Notify the FPGA fabric that the microprocessor unit (MPU) is in standby mode. "16">Wake up an MPCore processor from a wait for event (WFE) state. 	h2f_mpu_events
Enable general purpose signals	Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA fabric and the FPGA manager in the HPS portion of the SoC device.	h2f_gp
Enable Debug APB interface	Enables debug interface to the FPGA, allowing access to debug components in the HPS. For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	h2f_debug_apb h2f_debug_apb_sideband h2f_debug_apb_clock h2f_debug_apb_reset
Enable System Trace Macrocell hardware events	Enables system trace macrocell (STM) hardware events, allowing logic inside the FPGA to insert messages into the trace stream. For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	f2h_stm_hw_events
Enable FPGA Cross Trigger interface	Enables the cross trigger interface (CTI), which allows trigger sources and sinks to interface with the embedded cross trigger (ECT). For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	h2f_cti h2f_cti_clock

Parameter Name	Parameter Description	Interface Name
Enable FPGA Trace Port Interface Unit	Enables an interface between the trace port interface unit (TPIU) and logic in the FPGA. The TPIU is a bridge between on-chip trace sources and a trace port. For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	h2f_tpiu h2f_tpiu_clock_in h2f_tpiu_clock
Enable boot from FPGA signals	Enables an input to the HPS indicating whether a preloader is available in the on-chip memory of the FPGA. This option also enables a separate input to the HPS indicating a fallback preloader is available in the FPGA memory. A fallback preloader is used when there is no valid preloader image found in flash memory. For more information, refer to <i>Appendix A: Booting and Configuration</i> .	f2h_boot_from_fpga
Enable HLGPI Interface	Enables a general purpose interface that is connected to the General Purpose I/O (GPIO) peripheral of HPS. This is an input-only interface with 14-bit width. This interface shares the I/O pins with the HPS DDR SDRAM controller.	hps_io (hps_io_gpio_inst_HLGPI[0..13])

Related Information

- [CoreSight Debug and Trace](#) on page 11-1
Enabling the TPIU exposes trace signals to the device pins. Refer to the *CoreSight Debug and Trace* for more information.
- [Booting and Configuration](#) on page 31-1
For detailed information about the HPS boot sequence, refer to the *Booting and Configuration*.

FPGA-to-HPS SDRAM Interface

In the **FPGA-to-HPS SDRAM Interface** table, use + or – to add or remove FPGA-to-HPS SDRAM interfaces.

You can add one or more SDRAM ports that make the HPS SDRAM subsystem accessible to the FPGA fabric.

Table 28-2: FPGA-to-HPS SDRAM Port and Interface Names

Port Name	Interface Name
f2h_sdram0	f2h_sdram0_data f2h_sdram0_clock
f2h_sdram1	f2h_sdram1_data f2h_sdram1_clock
f2h_sdram2	f2h_sdram2_data f2h_sdram2_clock
f2h_sdram3	f2h_sdram3_data f2h_sdram3_clock
f2h_sdram4	f2h_sdram4_data f2h_sdram4_clock
f2h_sdram5	f2h_sdram5_data f2h_sdram5_clock

The following table shows the parameters available for each SDRAM interface where the **Name** parameter denotes the interface name.

Table 28-3: FPGA-to-HPS SDRAM Interface Parameters

Parameter Name	Parameter Description
Name	Port name (auto assigned as shown in Table 28-2 table below)
Type	Interface type: <ul style="list-style-type: none"> • AXI-3 • Avalon-MM Bidirectional • Avalon-MM Write-only • Avalon-MM Read-only
Width	32, 64, 128, or 256

Note: You can configure the slave interface to a data width of 32, 64, 128, or 256 bits. To facilitate accessing this slave from a memory-mapped master with a smaller address width, you can use the *Intel Address Span Extender*.

Related Information

DMA Peripheral Request

You can enable each direct memory access (DMA) controller peripheral request ID individually. Each request ID enables an interface for FPGA soft logic to request one of eight logical DMA channels to the FPGA.

Related Information

[DMA Controller](#) on page 17-1

For more information, refer to the *DMA Controller* chapter in the *Cyclone V Device Handbook, Volume 3*.

Interrupts

Table 28-4: FPGA-to-HPS Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable FPGA-to-HPS Interrupts	Enables the interface for FPGA interrupt signals to the MPU (in the HPS).	f2h_irq0 f2h_irq1

You can enable the interfaces for each HPS peripheral interrupt to the FPGA.

Table 28-5: HPS-to-FPGA Interrupts Interface

The following table lists the available HPS-to-FPGA interrupt interfaces and the corresponding parameters to enable them.

Parameter Name	Parameter Description	Interface Name
Enable CAN interrupts	Enables the interface for HPS CAN controllers interrupt to the FPGA	h2f_can0_interrupt h2f_can1_interrupt
Enable clock peripheral interrupts	Enables the interface for HPS clock manager and MPU wake-up interrupt signals to the FPGA	h2f_clkmgr_interrupt h2f_mpuwakeupt_interrupt
Enable CTI interrupts	Enables the interface for HPS cross-trigger interrupt signals to the FPGA	h2f_cti_interrupt0 h2f_cti_interrupt1

Parameter Name	Parameter Description	Interface Name
Enable DMA interrupts	Enables the interface for HPS DMA channels interrupt and DMA abort interrupt to the FPGA	h2f_dma_interrupt0 h2f_dma_interrupt1 h2f_dma_interrupt2 h2f_dma_interrupt3 h2f_dma_interrupt4 h2f_dma_interrupt5 h2f_dma_interrupt6 h2f_dma_interrupt7 h2f_dma_abort_interrupt
Enable EMAC interrupts	Enables the interface for HPS Ethernet MAC controller interrupt to the FPGA	h2f_emac0_interrupt h2f_emac1_interrupt
Enable FPGA manager interrupts	Enables the interface for the HPS FPGA manager interrupt to the FPGA	h2f_fpga_man_interrupt
Enable GPIO interrupts	Enables the interface for the HPS general purpose IO (GPIO) interrupt to the FPGA	h2f_gpio0_interrupt h2f_gpio1_interrupt h2f_gpio2_interrupt
Enable I ² C-EMAC interrupts (for I2C2 and I2C3)	Enables the interface for the HPS I ² C interrupt to the FPGA (I ² C used for EMAC media interface control)	h2f_i2c_emac0_interrupt h2f_i2c_emac1_interrupt
Enable I ² C peripheral interrupts (for I2C0 and I2C1)	Enables the interface for the HPS I ² C interrupt to the FPGA (I ² C used for general purpose)	h2f_i2c0_interrupt h2f_i2c1_interrupt
Enable L4 timer interrupts	Enables the interface for the HPS SP timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the <i>Timer</i> chapter in the <i>Cyclone V Device Handbook, Volume 3</i> .	h2f_l4sp0_interrupt h2f_l4sp1_interrupt
Enable NAND interrupts	Enables the interface for the HPS NAND controller interrupt to the FPGA	h2f_nand_interrupt

Parameter Name	Parameter Description	Interface Name
Enable OSC timer interrupts	Enables interface for the HPS OSC timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the <i>Timer</i> chapter in the <i>Cyclone V Device Handbook, Volume 3</i> .	h2f_osc0_interrupt h2f_osc1_interrupt
Enable Quad SPI interrupts	Enables interface for the HPS QSPI controller interrupt to the FPGA	h2f_qspi_interrupt
Enable SD/MMC interrupts	Enables the interface for the HPS SD/MMC controller interrupt to the FPGA	h2f_sdmmc_interrupt
Enable SPI master interrupts	Enables the interface for the HPS SPI master controller interrupt to the FPGA	h2f_spi0_interrupt h2f_spi1_interrupt
Enable SPI slave interrupts	Enables the interface for the HPS SPI slave controller interrupt to the FPGA	h2f_spi2_interrupt h2f_spi3_interrupt
Enable UART interrupts	Enables the interface for the HPS UART controller interrupt to the FPGA	h2f_uart0_interrupt h2f_uart1_interrupt
Enable USB interrupts	Enables the interface for the HPS USB controller interrupt to the FPGA	h2f_usb0_interrupt h2f_usb1_interrupt
Enable watchdog interrupts	Enables the interface for the HPS watchdog interrupt to the FPGA	h2f_wdog0_interrupt h2f_wdog1_interrupt

AXI Bridges

Table 28-6: Bridge Parameters

Parameter Name	Parameter Description	Interface Name
FPGA-to-HPS interface width	Enable or disable the FPGA-to-HPS interface; if enabled, set the data width to 32, 64, or 128 bits.	f2h_axi_slave f2h_axi_clock

Parameter Name	Parameter Description	Interface Name
HPS-to-FPGA interface width	Enable or disable the HPS-to-FPGA interface; if enabled, set the data width to 32, 64, or 128 bits.	h2f_axi_master h2f_axi_clock
Lightweight HPS-to-FPGA interface width	Enable or disable the lightweight HPS-to-FPGA interface. When enabled, the data width is 32 bits.	h2f_lw_axi_master h2f_lw_axi_clock

Note: To facilitate accessing these slaves from a memory-mapped master with a smaller address width, you can use the Intel Platform Designer (Standard) Address Span Extender.

Configuring HPS Clocks and Resets

The **HPS Clocks** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

[User Clocks](#) on page 28-8

[Reset Interfaces](#) on page 28-9

[PLL Reference Clocks](#) on page 28-10

[Peripheral FPGA Clocks](#) on page 28-11

User Clocks

When you enable a HPS-to-FPGA user clock, you must manually enter its maximum frequency for timing analysis. The Timing Analyzer has no other information about how software running on the HPS configures the phase-locked loop (PLL) outputs. Each possible clock, including clocks that are available from peripherals, has its own parameter for describing the clock frequency.

Note: Use the `set_global_assignment -name ENABLE_HPS_INTERNAL_TIMING ON` to enable timing analysis.

Related Information

[Selecting PLL Output Frequency and Phase](#) on page 28-15

User Clock Parameters

The frequencies that you provide are the maximum expected frequencies. The actual clock frequencies can be modified through the register interface, for example by software running on the microprocessor unit (MPU). For further details, refer to *Selecting PLL Output Frequency and Phase*.

Table 28-7: User Clock Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 0 clock	Enable main PLL from HPS-to-FPGA	h2f_user0_clock
User 0 clock frequency	Specify the maximum expected frequency for the main PLL	
Enable HPS-to-FPGA user 1 clock	Enable peripheral PLL from HPS-to-FPGA	h2f_user1_clock
User 1 clock frequency	Specify the maximum expected frequency for the peripheral PLL	
Enable HPS-to-FPGA user 2 clock	Enable SDRAM PLL from HPS-to-FPGA	h2f_user2_clock
User 2 clock frequency	Specify the maximum expected frequency for the SDRAM PLL	

Related Information

[Selecting PLL Output Frequency and Phase](#) on page 28-15

Clock Frequency Usage

The clock frequencies you provide are reported in a Synopsys Design Constraints File (.sdc) generated by Platform Designer (Standard). The .sdc file will be referenced in the system .qip file when the system is generated.

Reset Interfaces

You can enable the resets on an individual basis through the **FPGA Interfaces** tab under the **Resets** section.

Table 28-8: Reset Parameters

Parameter Name	Parameter Description	Interface Name
Enable HPS-to-FPGA cold reset output	Enable interface for HPS-to-FPGA cold reset output	h2f_cold_reset

Parameter Name	Parameter Description	Interface Name
Enable HPS warm reset handshake signals	Enable an additional pair of reset handshake signals allowing soft logic to notify the HPS when it is safe to initiate a warm reset in the FPGA fabric.	h2f_warm_reset_handshake
Enable FPGA-to-HPS debug reset request	Enable interface for FPGA-to-HPS debug reset request	f2h_debug_reset_req
Enable FPGA-to-HPS warm reset request	Enable interface for FPGA-to-HPS warm reset request	f2h_warm_reset_req
Enable FPGA-to-HPS cold reset request	Enable interface for FPGA-to-HPS cold reset request	f2h_cold_reset_req

Related Information

PLL Reference Clocks

Table 28-9: PLL Reference Clock Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable FPGA-to-HPS peripheral PLL reference clock	Enable the interface for FPGA fabric to supply reference clock to HPS peripheral PLL	f2h_periph_ref_clock
Enable FPGA-to-HPS SDRAM PLL reference clock	Enable the interface for FPGA fabric to supply reference clock to HPS SDRAM PLL	f2h_sdram_ref_clock

Related Information

[Clock Manager](#) on page 3-1

For general information about clock signals, refer to the *Clock Manager* chapter in the *Cyclone V Device Handbook, Volume 3*.

Peripheral FPGA Clocks

Table 28-10: Peripheral FPGA Clock Parameters

Parameter Name	Parameter Description
EMAC 0 (emac0_md_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 MDIO clock frequency
EMAC 0 (emac0_gtx_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 transmit clock frequency
EMAC 1 (emac1_md_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 MDIO clock frequency
EMAC 1 (emac1_gtx_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 transmit clock frequency
QSPI (qspi_sclk_out clock frequency)	If QSPI peripheral is routed to FPGA, use the input field to specify QSPI serial clock frequency
SPIM 0 (spim0_sclk_out clock frequency)	If SPI master 0 peripheral is routed to FPGA, use the input field to specify SPI master 0 output clock frequency
SPIM 1 (spim1_sclk_out clock frequency)	If SPI master 1 peripheral is routed to FPGA, use the input field to specify SPI master 1 output clock frequency
I ² C0 (i2c0_clk clock frequency)	If I ² C 0 peripheral is routed to FPGA, use the input field to specify I ² C 0 output clock frequency
I ² C1 (i2c1_clk clock frequency)	If I ² C 1 peripheral is routed to FPGA, use the input field to specify I ² C 1 output clock frequency
I ² C2 (i2c2_clk clock frequency)	If I ² C 2 peripheral is routed to FPGA, use the input field to specify I ² C 2 output clock frequency
I ² C3 (i2c3_clk clock frequency)	If I ² C 3 peripheral is routed to FPGA, use the input field to specify I ² C 3 output clock frequency

Configuring Peripheral Pin Multiplexing

The **Peripheral Pin Multiplexing** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

[Configuring Peripherals](#) on page 28-12

[Connecting Unassigned Pins to GPIO](#) on page 28-12

[Using Unassigned IO as LoanIO](#) on page 28-13

You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional IO.

[Resolving Pin Multiplexing Conflicts](#) on page 28-13

Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

[Peripheral Signals Routed to FPGA](#) on page 28-14

Configuring Peripherals

The **Peripheral Pin Multiplexing** tab contains a group of parameters for each available type of peripheral. You can enable one or more instances of each peripheral type by selecting an HPS I/O pin set for each instance. When enabled, some peripherals also have mode settings specific to their functions.

When you assign a peripheral to an HPS I/O pin set, the corresponding peripheral is highlighted in the **Peripherals MUX Table** at the end of **Peripheral Pin Multiplexing** tab. The other unused peripheral pin set remains un-highlighted in the table.

Each list in the **Peripheral Pin Multiplexing** tab has a hint describing in detail the options available in the list. The hint for each mode list shows the signals used by each available mode. View each hint by hovering over the corresponding mode list.

You can enable the following types of peripherals. For details of peripheral-specific settings, refer to the chapter for each peripheral:

- [CAN Controller](#) on page 26-1

Connecting Unassigned Pins to GPIO

For pins that are not assigned to any peripherals, you can assign them to the GPIO peripheral by clicking on the corresponding GPIO push button in the table. Click on the selected push button to remove GPIO pin assignment. The table also shows the GPIO bit number that correlates to the I/O pins.

Using Unassigned IO as LoanIO

You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional IO.

Each LoanIO port has an input, output, and output enable, which directly controls the HPS IO functions. The LoanIO only operates when the HPS registers have been set up in the pre-loader to allow their operation. The LoanIO are asynchronous, thus no clocking is required.

The status of the LoanIO in the duration after HPS I/O is configured and before the FPGA is configured is as follows: When the FPGA powers up and is "not" configured, inputs into the HPS from the FPGA are driven to a logical 1. When the FPGA is configured the signal may toggle, and then will take on whatever level the FPGA user design drives out.

Use the following steps to enable the LoanIO signals:

1. Select the **Peripheral Pins Multiplexing** tab in the HPS parameter editor.
2. Choose the corresponding LoanIO pins from the **Peripherals Mux Table**, and click the push button to select/unselect it.
3. Export the peripheral signals out of the Platform Designer (Standard) system.
4. In the Quartus Prime software, connect the user logic to the LoanIO interface to drive the HPS IOs.

Table 28-11: Generated Conduit Signal Interface

Conduit Name	Direction	Declarations
._hps_io_gpio_inst_LOANIOXX	Bi-direction	User must declare as a top-level pin; pin assignment is hardcoded following the HPS IO location.
._h2f_loan_io_in	Out	HPS IO data input signal, output to FPGA user logic.
._h2f_loan_io_out	In	HPS IO data output signal, input from FPGA user logic.
._h2f_loan_io_oe	In	HPS IO data output enable signal, input from FPGA user logic.

Platform Designer (Standard) will generate a full signal array for `h2f_loan_io_in`, `h2f_loan_io_out`, and `h2f_loan_io_oe`. You must assign user logic to the specific signal array. For example, you have triggered LoanIO 40, so its respective signal array is `h2f_loan_io_in[40]`, `h2f_loan_io_out[40]`, and `h2f_loan_io_oe[40]`.

Resolving Pin Multiplexing Conflicts

Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

Pins that have multiple peripherals assigned to them are highlighted in red color with the conflicting peripherals in boldface font style. Solve the multiplexing conflicts by de-selecting peripherals that are assigned to the pins, leaving only one peripheral, which is needed.

Peripheral Signals Routed to FPGA

You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

The following steps show you how to enable the peripheral signals:

1. Select FPGA in the peripheral pin multiplexing selection drop-down box.
2. Export the peripheral signals out of Platform Designer (Standard) system.
3. In the Intel Quartus Prime software, connect the signals to the FPGA I/O pins.

Note: When routed to the FPGA, some HPS peripherals require additional pipeline support in the connected soft logic. Routing into the FPGA circumvents the pipelining available in the HPS I/O. Refer to the relevant HPS peripheral chapter for details.

Configuring the External Memory Interface

The **SDRAM** tab is one of four tabs on the HPS component. This tab contains the PLL output frequency and phase group.

The HPS supports one memory interface implementing double data rate 2 (DDR2), double data rate 3 (DDR3), and low-power double data rate 2 (LPDDR2) protocols. The interface can be up to 40 bits wide with optional error correction code (ECC).

Configuring the HPS SDRAM controller is similar to configuring any other SDRAM controller in Platform Designer (Standard). There are several important differences:

- The HPS parameter editor supports all SDRAM protocols with one tab. When you parameterize the SDRAM controller, you must specify the memory protocol: DDR2, DDR3, or LPDDR2.

To select the memory protocol, select DDR2, DDR3, or LPDDR2 from the **SDRAM Protocol** list in the **SDRAM** tab. After you select the protocol, settings not applicable to that protocol are disabled.

- Many HPS SDRAM controller settings are the same as for Intel dedicated DDR2, DDR3, and LPDDR2 controllers. This section only describes SDRAM parameters that are specific to the HPS component.
- Because the HPS memory controller is not configurable through the Quartus Prime software, the Controller and Diagnostic tabs are not present in the HPS parameter editor.
- Some settings, such as the controller settings, are not included because they can only be configured through the register interface, for example by software running on the MPU.
- Unlike the memory interface clocks in the FPGA, the memory interface clocks for the HPS are initialized by the boot-up code using values provided by the configuration process. You can accept the values provided by UniPHY, or you can use your own PLL settings, as described in *Selecting PLL Output Frequency and Phase*.

Note: The HPS does not support external memory interface (EMIF) synthesis generation, compilation, or timing analysis.

The HPS memory controller cannot be bonded with a memory controller on the FPGA portion of the device.

For detailed information about SDRAM controller parameters, refer to the following chapters:

- [SDRAM Controller Subsystem](#) on page 12-1

Selecting PLL Output Frequency and Phase

You select PLL output frequency and phase with controls in the **PHY Settings** tab. In the HPS, PLL frequencies and phases are set by software at system startup. A PLL might not be able to produce the exact frequency that you specify in **Memory clock frequency**. Normally, the Quartus Prime software sets **Achieved memory clock frequency** to the closest achievable frequency, using an algorithm that tries to balance frequency accuracy against clock jitter. This clock frequency is used for timing analysis by the Timing Analyzer.

It is possible to use a different software algorithm for configuring the PLLs. You can force the **Achieved memory clock frequency** box to take on the same value as **Memory clock frequency**, by turning on **Use specified frequency instead of calculated frequency** in the **PHY Settings** tab, under **Clocks**.

Note: If you turn on **Use specified frequency instead of calculated frequency**, the Quartus Prime software assumes that the value in the **Achieved memory clock frequency** box is correct. If it is not, timing analysis results are incorrect.

Using the Address Span Extender Component

The FPGA-to-HPS bridge and FPGA-to-HPS SDRAM memory-mapped interfaces expose their entire 4-GB address spaces to the FPGA fabric. The address span extender component provides a memory-mapped window into the address space that it masters. Using the address span extender, you can expose portions of the HPS memory space without needing to expose the entire 4 GB address space.

You can use the address span extender between a soft logic master and an FPGA-to-HPS bridge or FPGA-to-HPS SDRAM interface. This component reduces the number of address bits required for a master to address a memory-mapped slave interface located in the HPS.

Figure 28-2: Address Span Extender Components

Two address span extender components used in a system with the HPS.

You can also use the address span extender in the HPS-to-FPGA direction, for slave interfaces in the FPGA. In this case, the HPS-to-FPGA bridge exposes a limited, variable address space in the FPGA, which can be paged in using the address span extender.

For example, suppose that the HPS-to-FPGA bridge has a 1-GB span, and the HPS needs to access three independent 1-GB memories in the FPGA portion of the device. To achieve this, the HPS programs the address span extender to access one SDRAM (1-GB) in the FPGA at a time. This technique is commonly called paging or windowing.

For more information about the address span extender, refer to *Bridges* in the *Platform Designer (Standard) Interconnect and System Design Components* chapter in the *Quartus® Prime Handbook*.

Generating and Compiling the HPS Component

The process of generating and compiling an HPS design is very similar to the process for any other Platform Designer (Standard) project. Perform the following steps:

1. Generate the design with Platform Designer (Standard). The generated files include an `.sdc` file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add `<system_name>.qip` to the Quartus Prime project. `<qsys_system_name>.qip` is the Quartus Prime IP file for the HPS component, generated by Platform Designer (Standard).
3. Perform analysis and synthesis with the Quartus Prime software.
4. Assign constraints to the SDRAM component. When Platform Designer (Standard) generates the HPS component (step 1), it generates the pin assignment Tcl Script File (`.tcl`) to perform memory assignments. The script file name is `<system_name>_pin_assignments.tcl`, where

<system_name> is the name of your Platform Designer (Standard) system. Run this script to assign constraints to the SDRAM component.

Note: For information about running the pin assignment script, refer to “IP catalog” in the *Implementing and Parameterizing Memory IP* chapter in the *External Memory Interface Handbook*.

You do not need to specify pin assignments other than memory assignments. When you configure pin multiplexing as described in *Configuring Peripheral Pin Multiplexing* section, you implicitly make pin assignments for all HPS peripherals. Each peripheral is routed exclusively to the pins you specify. HPS I/O signals are exported to the top level of the Platform Designer (Standard) design, with information enabling the Quartus Prime software to make pin assignments automatically.

You can view and modify the assignments in the **Peripheral Pin Multiplexing** tab. You can also view the assignments in the Quartus fitter report.

5. Compile the design with the Quartus Prime software.
6. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

HPS Component Interfaces 29

2020.01.13

cv_5v4

Subscribe

Send Feedback

This chapter describes the interfaces, including clocks and resets, implemented by the hard processor system (HPS) component.

The majority of the resets can be enabled on an individual basis. The exception is the `h2f_reset` interface, which is always enabled.

You must declare the clock frequency of each HPS-to-FPGA clock for timing purposes. Each possible clock, including ones that are available from peripherals, has its own parameter for describing the clock frequency. Declaring the clock frequency for HPS-to-FPGA clocks specifies how you plan to configure the PLLs and peripherals, to enable the Timing Analyzer to accurately estimate system timing. It has no effect on PLL settings.

Related Information

For information about instantiating the HPS component, refer to the *Instantiating the HPS Component* chapter.

Memory-Mapped Interfaces

FPGA-to-HPS Bridge

Table 29-1: FPGA-to-HPS Bridges and Clocks

Interface Name	Description	Associated Clock Interface
<code>f2h_axi_slave</code>	FPGA-to-HPS AXI slave interface	<code>f2h_axi_clock</code>

The FPGA-to-HPS interface is a configurable data width AXI slave allowing FPGA masters to issue transactions to the HPS. This interface allows the FPGA fabric to access the majority of the HPS slaves. This interface also provides a coherent memory interface.

ALTERA
now part of Intel

The FPGA-to-HPS interface is an AXI-3 compliant interface with the following features:

- Configurable data width: 32, 64, or 128 bits
- Accelerator Coherency Port (ACP) sideband signals
- HPS-side AXI bridge to manage clock crossing, buffering, and data width conversion

Other interface standards in the FPGA fabric, such as connecting to Avalon® Memory-Mapped (Avalon-MM) interfaces, can be supported through the use of soft logic adapters. The Platform Designer (Standard) system integration tool automatically generates adapter logic to connect AXI to Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Intel Address Span Extender.

Related Information

ACP Sideband Signals

For communication with the ACP on the microprocessor unit (MPU) subsystem, AXI sideband signals are used to describe the inner cacheable attributes for the transaction.

Related Information

[Cortex-A9 MPCore](#) on page 10-4

For more information about the ACP sideband signals, refer to the *Cortex-A9 MPU Subsystem* chapter.

HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges

Table 29-2: HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges and Clocks

Interface Name	Description	Associated Clock Interface
h2f_axi_master	HPS-to-FPGA AXI master interface	h2f_axi_clock
h2f_lw_axi_master	HPS-to-FPGA lightweight AXI master interface	h2f_lw_axi_clock

The HPS-to-FPGA interface is a configurable data width AXI master (32-, 64-, or 128-bit) that allows HPS masters to issue transactions to the FPGA fabric.

The lightweight HPS-to-FPGA interface is a 32-bit AXI master that allows HPS masters to issue transactions to the FPGA fabric.

Both HPS-to-FPGA interfaces are AXI-3 compliant. The HPS-side AXI bridges manage clock crossing, buffering, and data width conversion where necessary.

Other interface standards in the FPGA fabric, such as connecting to Avalon-MM interfaces, can be supported through the use of soft logic adapters. The Platform Designer (Standard) system integration tool automatically generates adaptor logic to connect AXI to Avalon-MM interfaces.

Each AXI bridge accepts a clock input from the FPGA fabric and performs clock domain crossing internally. The exposed AXI interface operates on the same clock domain as the clock supplied by the FPGA fabric.

Related Information

- [Clocks](#) on page 29-4

- For more information, refer to the *HPS FPGA AXI Bridges Component* chapter.

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface is a direct connection between the FPGA fabric and the HPS SDRAM controller. This interface is highly configurable, allowing a mix between number of ports and port width. The interface supports both AXI-3 and Avalon-MM protocols.

Table 29-3: FPGA-to-HPS SDRAM Interfaces and Clocks

Interface Name	Description	Associated Clock Interface
f2h_sdram0_data	SDRAM AXI or Avalon-MM port 0	f2h_sdram0_clock
f2h_sdram1_data	SDRAM AXI or Avalon-MM port 1	f2h_sdram1_clock
f2h_sdram2_data	SDRAM AXI or Avalon-MM port 2	f2h_sdram2_clock
f2h_sdram3_data	SDRAM AXI or Avalon-MM port 3	f2h_sdram3_clock
f2h_sdram4_data	SDRAM AXI or Avalon-MM port 4	f2h_sdram4_clock
f2h_sdram5_data	SDRAM AXI or Avalon-MM port 5	f2h_sdram5_clock

The FPGA-to-HPS SDRAM interface is a configurable interface to the multi-port SDRAM controller.

The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction. The interface is implemented as four 64-bit read ports and four 64-bit write ports. As a result, the minimum data width used by the interface is 64 bits, regardless of the number or type of interfaces.

You can configure this interface the following ways:

- AXI-3 or Avalon-MM protocol
- Number of interfaces
- Data width of interfaces

The FPGA-to-HPS SDRAM interface supports six command ports, allowing up to six Avalon-MM interfaces or three bidirectional AXI interfaces.

Each command port is available either to implement a read or write command port for AXI, or to form part of an Avalon-MM interface.

You can use a mix of Avalon-MM and AXI interfaces, limited by the number of command/data ports available. Some AXI features are not present in Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Address Span Extender.

Note: If you connect the HPS-to-SDRAM interface with the Avalon MM pipeline bridge, you will to set the bridge **Addressing Unit** setting to **Word**.

Related Information

- [Clocks](#) on page 29-4

- For information about the address span extender, refer to “Using the Address Span Extender Component” in the *Instantiating the HPS Component* chapter.

Clocks

The HPS-to-FPGA clock interface supplies physical clocks to the FPGA. These clocks and resets are generated in the HPS.

Alternative Clock Inputs to HPS PLLs

This section lists alternative clock inputs to HPS PLLs.

- `f2h_periph_ref_clock`—FPGA-to-HPS peripheral PLL reference clock. You can connect this clock input to a clock in your design that is driven by the clock network on the FPGA side.
- `f2h_sdram_ref_clock`—FPGA-to-HPS SDRAM PLL reference clock. You can connect this clock to a clock in your design that is driven by the clock network on the FPGA side.

User Clocks

A user clock is a PLL output that is connected to the FPGA fabric rather than the HPS. You can connect a user clock to logic that you instantiate in the FPGA fabric.

- `h2f_user0_clock`—HPS-to-FPGA user clock, driven from main PLL
- `h2f_user1_clock`—HPS-to-FPGA user clock, driven from peripheral PLL
- `h2f_user2_clock`—HPS-to-FPGA user clock, driven from SDRAM PLL

Note: At power-up or reset, when `CSEL[3:0]=0x0` or `BSEL[2:0]` is configured to boot from FPGA, the HPS PLLs are in bypass mode. Thus, HPS user clocks exported to the FPGA fabric run at `osc1_clk` frequency. For more information refer to the *Clock Selection* section.

Related Information

[Clock Select](#) on page 31-25

The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

AXI Bridge FPGA Interface Clocks

The AXI interface has an asynchronous clock crossing in the FPGA-to-HPS bridge. The FPGA-to-HPS and HPS-to-FPGA interfaces are synchronized to clocks generated in the FPGA fabric. These interfaces can be asynchronous to one another. The SDRAM controller's multiport front end (MPFE) transfers the data between the FPGA and HPS clock domains.

- `f2h_axi_clock`—AXI slave clock for FPGA-to-HPS bridge, generated in FPGA fabric
- `h2f_axi_clock`—AXI master clock for HPS-to-FPGA bridge, generated in FPGA fabric
- `h2f_lw_axi_clock`—AXI master clock for lightweight HPS-to-FPGA bridge, generated in FPGA fabric

SDRAM Clocks

You can configure the HPS component with up to six FPGA-to-HPS SDRAM clocks.

Each command channel to the SDRAM controller has an individual clock source from the FPGA fabric. The interface clock is always supplied by the FPGA fabric, with clock crossing occurring on the HPS side of the boundary.

The FPGA-to-HPS SDRAM clocks are driven by soft logic in the FPGA fabric.

- `f2h_sdram0_clock`—SDRAM clock for port 0
- `f2h_sdram1_clock`—SDRAM clock for port 1
- `f2h_sdram2_clock`—SDRAM clock for port 2
- `f2h_sdram3_clock`—SDRAM clock for port 3
- `f2h_sdram4_clock`—SDRAM clock for port 4
- `f2h_sdram5_clock`—SDRAM clock for port 5

Peripheral FPGA Clocks

The HPS peripheral clocks are exposed when the peripheral signals are routed to the FPGA.

Table 29-4: Peripheral FPGA Clocks

Clock Name	Description
<code>emac_md_clk</code>	Ethernet PHY management interface clock
<code>emac_gtx_clk</code>	Ethernet transmit clock that is used by the PHY in GMII mode
<code>emac_rx_clk_in</code>	Ethernet MAC reference clock from the PHY
<code>emac_tx_clk_in</code>	Ethernet MAC uses this clock input for TX reference

Clock Name	Description
emac_ptp_ref_clock	Ethernet timestamp precision time protocol (PTP) reference clock
qspi_sclk_out	QSPI master clock output
spim_sclk_out	SPI master serial clock output
spis_sclk_in	SPI slave serial clock input
i2c_clk	I ² C outgoing clock (part of the SCL bidirectional pin signals)
i2c_scl_in	I ² C incoming clock (part of the SCL bidirectional pin signals)

Resets

This section describes the reset interfaces to the HPS component.

Related Information

[Reset Manager](#) on page 4-1

For details about the HPS reset sequences, refer to the *Functional Description of the Reset Manager* in the *Reset Manager* chapter .

HPS-to-FPGA Reset Interfaces

The following interfaces allow the HPS to reset soft logic in the FPGA fabric:

- `h2f_reset`—HPS-to-FPGA warm reset
- `h2f_cold_reset`—HPS-to-FPGA cold reset
- `h2f_warm_reset_handshake`—Warm reset request and acknowledge interface between HPS and FPGA

HPS External Reset Request

The following interfaces allow soft logic in the FPGA fabric to request for different types of HPS resets:

- `f2h_cold_reset_req`—FPGA-to-HPS cold reset request
- `f2h_warm_reset_req`—FPGA-to-HPS warm reset request
- `f2h_dbg_reset_req`—FPGA-to-HPS debug reset request

Peripheral Reset Interfaces

The following are Ethernet reset interfaces, that can be used when the Ethernet is routed to the FPGA:

- `emac_tx_reset`— Ethernet transmit clock reset output used to reset external PHY TX clock domain logic
- `emac_rx_reset`— Ethernet receive clock reset output used to reset external PHY RX clock domain logic

Debug and Trace Interfaces

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and a trace port.

- `h2f_tpiu`
- `h2f_tpiu_clock_in`
- `h2f_tpiu_clock`

FPGA System Trace Macrocell Events Interface

The system trace macrocell (STM) hardware events allow logic in the FPGA to insert messages into the trace stream.

- `f2h_stm_hw_events`

FPGA Cross Trigger Interface

The cross trigger interface (CTI) allows trigger sources and sinks to interface with the embedded cross trigger (ECT).

- `h2f_cti`
- `h2f_cti_clock`

Debug APB Interface

The debug Advanced Peripheral Bus (APB) interface allows debug components in the FPGA fabric to debug components on the CoreSight debug APB.

- `h2f_debug_apb`
- `h2f_debug_apb_sideband`
- `h2f_debug_apb_reset`
- `h2f_debug_apb_clock`

Peripheral Signal Interfaces

DMA Controller Interface

The DMA controller interface allows soft IP in the FPGA fabric to communicate with the DMA controller in the HPS. You can configure up to eight separate interface channels.

- `f2h_dma_req0`—FPGA DMA controller peripheral request interface 0
- `f2h_dma_req1`—FPGA DMA controller peripheral request interface 1
- `f2h_dma_req2`—FPGA DMA controller peripheral request interface 2
- `f2h_dma_req3`—FPGA DMA controller peripheral request interface 3
- `f2h_dma_req4`—FPGA DMA controller peripheral request interface 4
- `f2h_dma_req5`—FPGA DMA controller peripheral request interface 5
- `f2h_dma_req6`—FPGA DMA controller peripheral request interface 6
- `f2h_dma_req7`—FPGA DMA controller peripheral request interface 7

Each of the DMA peripheral request interface contains the following three signals:

- `f2h_dma_req`—This signal is used to request burst transfer using the DMA
- `f2h_dma_single`—This signal is used to request single word transfer using the DMA
- `f2h_dma_ack`—This signal indicates the DMA acknowledgment upon requests from the FPGA

For more information, refer to *Cortex-A9 MPU Subsystem* .

MPU Standby and Event Interfaces

MPU standby signals are notification signals to the FPGA fabric that the MPU is in standby. Event signals are used to wake up the Cortex-A9 processors from a wait for event (WFE) state. The following shows the signals in the interface:

- `h2f_mpu_events`—MPU standby and event interface, including the following signals.
- `h2f_mpu_eventi`—Sends an event from logic in the FPGA fabric to the MPU. This FPGA-to-HPS signal is used to wake up a processor that is in a Wait For Event state. Asserting this signal has the same effect as executing the `SEV` instruction in the Cortex-A9. This signal must be de-asserted until the FPGA fabric is powered-up and configured.
- `h2f_mpu_evento`—Sends an event from the MPU to logic in the FPGA fabric. This HPS-to-FPGA signal is asserted when an `SEV` instruction is executed by one of the Cortex-A9 processors.
- `h2f_mpu_standbywfe[1:0]`—Indicates which Cortex-A9 processor is in the WFE state
- `h2f_mpu_standbywfi[1:0]`—Indicates which Cortex-A9 processor is in the wait for interrupt (WFI) state

The MPU provides signals to indicate when it is in a standby state. These signals are available to custom hardware designs in the FPGA fabric.

Related Information

[Cortex-A9 MPCore](#) on page 10-4

For more information, refer to *Cortex-A9 MPU Subsystem* .

General Purpose Signals

h2f_mpu_gp—General purpose interface

FPGA-to-HPS Interrupts

You can configure the HPS component to provide 64 general purpose FPGA-to-HPS interrupts, allowing soft IP in the FPGA fabric to trigger interrupts to the MPU's generic interrupt controller (GIC). The interrupts are implemented through the following 32-bit interfaces:

- f2h_irq0—FPGA-to-HPS interrupts 0 through 31
- f2h_irq1—FPGA-to-HPS interrupts 32 through 63

The FPGA-to-HPS interrupts are asynchronous on the FPGA interface. Inside the HPS, the interrupts are synchronized to the MPU's internal peripheral clock (`periphclk`).

Related Information

[HPS Component Interfaces](#) on page 29-1

There are various HPS peripherals to FPGA interrupt interfaces that you can configure. To learn the complete list of interfaces, refer to the *Instantiating the HPS Component* chapter.

Boot from FPGA Interface

You can enable the boot from FPGA interface to indicate the availability of preloader software in the FPGA memory. This interface is used to indicate the availability of a fallback preloader software in FPGA memory as well. The fallback preloader is used when there is no valid preloader image found in HPS flash memories.

Input-only General Purpose Interface

You can enable a general purpose interface that is connected to the general purpose I/O (GPIO) peripheral of the HPS. This is an input-only interface with 14-bit wide width. The interface share the same I/O pins with the HPS DDR SDRAM controller.

Simulating the HPS Component 30

Send Feedback

This section describes the simulation support for the hard processor system (HPS) component. The HPS simulation models provide bus functional models of the HPS and FPGA fabric and a simulation model of the interface to SDRAM memory.

The HPS simulation support does not include modules implemented in the HPS, such as the Arm Cortex-A9 MPCore processor.

The simulation support files are specified when the HPS component is instantiated in the Platform Designer (Standard) system integration tool. When you enable a particular HPS-FPGA interface, Platform Designer (Standard) provides the corresponding model during the generation process.

The HPS simulation support enables you to develop and verify your own FPGA user logic or intellectual property (IP) that interfaces to the HPS component.

The simulation model supports the following interfaces:

- Clock and reset interfaces
- FPGA-to-HPS Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) slave interface
- HPS-to-FPGA AXI master interface
- Lightweight HPS-to-FPGA AXI master interface
- FPGA-to-HPS SDRAM interface
- Microprocessor unit (MPU) general-purpose I/O (GPIO) interface
- MPU standby and event interface
- Interrupts interface
- Direct memory access (DMA) controller peripheral request interface
- Debug Advanced Peripheral Bus (APB) interface
- System Trace Macrocell (STM) hardware event
- FPGA cross trigger interface (CTI)
- FPGA trace port interface unit (TPIU)
- Boot from FPGA interface
- Input-only general purpose interface

Figure 30-1: HPS BFM Block Diagram

The HPS BMFs use standard function calls from the BFM application programming interface (API), as detailed in the remainder of this chapter.

HPS simulation supports only Verilog HDL or SystemVerilog simulation environments. Users with VHDL Custom IP can run BFM simulations so long as a mixed-language simulation license is available on their chosen simulator.

Simulation Flows

Intel provides a functional register transfer level (RTL) simulation and a post-fitter gate-level simulation flow. Both simulation flows involve the following major steps, which is defined in the following sections:

1. Setting up the HPS component for simulation.
2. Generating the HPS simulation model in Platform Designer (Standard).
3. Running the simulation.

Related Information

[Simulating Altera FPGA Designs](#)

For general information about simulation, refer to the *Simulating Altera FPGA Designs* chapter in volume 3 of the *Quartus Prime Standard Edition Handbook*.

Setting Up the HPS Component for Simulation

The following steps outline how to set up the HPS component for simulation.

1. Add the HPS component from the Platform Designer (Standard) Component Library.
2. Configure the component based on your application needs by selecting or deselecting the HPS-FPGA interfaces.
3. Connect the appropriate HPS interfaces to other components in the system. For example, connect the FPGA-to-HPS AXI slave interface to an AXI or Avalon-MM master interface in another component in the system.

When you create your component, make sure the conduit interfaces have the correct role names and widths. Also make sure the conduit interfaces are opposite in direction to what is shown in the HPS Conduit Interfaces table.

Generating the HPS Simulation Model in Platform Designer (Standard)

The following steps outline how to generate the simulation model:

1. In Platform Designer (Standard), click **Generate HDL** under the Generate menu.
2. Choose between RTL and post-fit simulation
For RTL simulation, perform the following steps:
 - a. Set **Create simulation model** to Verilog.
 - b. Click **Generate**.⁽⁶⁷⁾For post-fit simulation, perform the following steps:
 - a. Turn on the **Create HDL design files for synthesis** option.
 - b. Turn on the **Create block symbol file (.bsf)** option.⁽⁶⁸⁾⁽⁶⁹⁾
3. Click **Generate**.

Related Information

- [Instantiating the HPS Component](#) on page 28-1
- [Creating a System with Platform Designer \(Standard\)](#)

For more information about Platform Designer (Standard) simulation, refer to “Simulating a Platform Designer (Standard) System” in the *Creating a System with Platform Designer (Standard)* chapter in volume 1 of the *Quartus Prime Handbook*.

Running the Simulations

The steps to run a simulation depend on whether you are running an RTL simulation or a post-fit simulation.

⁽⁶⁷⁾ VHDL is supported for HPS simulation and it requires a mix language simulator. However, the BFM's always need to be in verilog. Custom components can be in VHDL.

⁽⁶⁸⁾ A **.bsf** file is only needed for schematic entry.

⁽⁶⁹⁾ This is not a requirement for simulation or implementation unless a schematic is used.

Running HPS RTL Simulation

Platform Designer (Standard) generates scripts for several simulators that you can use to complete the simulation process, as listed in the following table.

Table 30-10: Platform Designer (Standard)-Generated Scripts for Supported Simulators

Simulator	Script Name	Directory
Mentor Graphics* ModelSim	msim_ setup.tcl	<i><project directory>/<design name>/simulation/mentor</i>
Cadence NC-Sim	ncsim_ setup.sh	<i><project directory>/<design name>/simulation/cadence</i>
Synopsys VCS	vcs_setup.sh	<i><project directory>/<design name>/simulation/synopsys/ vcs</i>
Synopsys VCS-MX	vcsmx_ setup.sh	<i><project directory>/<design name>/simulation/synopsys/ vcsmx</i>

Running HPS Post-Fit Simulation

To run HPS post-fit simulation after successful Platform Designer (Standard) generation, perform the following steps:

1. Add the generated synthesis file set to your Intel Quartus Prime project by performing the following steps:
 - a. In the Quartus Prime software, click **Settings** in the Assignments menu.
 - b. In the **Settings <your system name>** dialog box, on the **Files** tab, browse to *<your project directory>/<your system name>/synthesis/* and select *<your system name>.qip*.
 - c. Click **Open**. The **Select File** dialog box closes.
 - d. Click **OK**. The **Settings** dialog box closes.
2. Optionally instantiate your HPS system as the top-level entity in your Intel Quartus Prime project.
3. Compile the design by clicking **Start Compilation** in the Processing menu.
4. Change the EDA Netlist Writer settings, if necessary, by performing the following steps:
 - a. Click **Settings** in the Assignment menu.
 - b. On the **Simulation** tab, under the **EDA Tool Settings** tab, you can specify the following EDA Netlist Writer settings:

- **Tool name**—The name of the simulation tool
 - **Format for output netlist**
 - **Output directory**
- c. Click **OK**.
5. To create the post-fitter simulation model with Quartus Prime EDA Netlist Writer, perform the following steps:
 - a. Click **Start** in the Processing menu.
 - b. Click **Start EDA Netlist Writer**.

[Quartus Prime Help](#)

Post-Fit Simulation Files

Post-fit simulation is the simulation of the netlist generated from the original RTL design after it has been mapped, synthesized, and fit. The netlist represents the actual hardware and its connections as they appear in the FPGA. Quartus Prime generates the netlist and can generate a Standard Delay Format (.sdf) file with the timing information for all connections. The simulation can be functional only (without the timing information) where all wires and gates take zero time, or it can be a timing simulation where the time for all transitions is based on the SDF information.

Post-fit simulation can serve a number of different purposes. It can be used to perform a dynamic verification of the timing of the design, or it can be used to verify the functional correctness of either the design, the compilation flow (in particular, the fitter), or both.

This table uses the following symbols:

BFM API Hierarchy Format

For post-fit simulation, you must call the BFM API in your test program with a specific hierarchy. The hierarchy format is:

```
<DUT>.\<HPS>|fpga_interfaces|<interface><space>.<BFM>.<API function>
```

Where:

- *<DUT>* is the instance name of the design under test that you instantiated in your test bench . The design under test is the HPS component.
- *<HPS>* is the HPS component instance name that you use in your Platform Designer (Standard) system.
- *<interface>* is the instance name of a specific FPGA-to-HPS or HPS-to-FPGA interface. This name can be found in the **fpga_interfaces.sv** file located in *<project directory>/<design name>/synthesis/submodules*.
- *<space>*—You must insert one space character after the interface instance name.
- *<BFM>* is the BFM instance name. To identify the BFM instance name, in *<ACDS install>/ip/altera/hps/postfitter_simulation*, find the SystemVerilog file corresponding to the interface type that you are using. This SystemVerilog file contains the BFM instance name.

For example, a path for the Lightweight HPS-to-FPGA master interface hierarchy could be formed as follows:

```
top.dut.\my_hps_component|fpga_interface|hps2fpga_light_weight .h2f_lw_axi_master
```

Notice the space after `hps2fpga_light_weight`. Omitting this space would cause simulation failure because the instance name `hps2fpga_light_weight` , including the space, is the name used in the post-fit simulation model generated by the Intel Quartus Prime software.

Clock and Reset Interfaces

Clock Interface

Platform Designer (Standard) generates the BFM clock for each clock input interface from the FPGA component. For the FPGA-to-HPS PLL reference clocks, specify the BFM reference clock frequency in the **Reference clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Platform Designer (Standard).

Table 30-12: HPS Clock Input Interface Simulation Model

The Intel clock source BFM application programming interface (API) applies to all the BFMs listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
f2h_periph_ref_clock	f2h_periph_ref_clock_inst
f2h_sdram_ref_clock	f2h_sdram_ref_clock_inst

Platform Designer (Standard) generates the clock source BFM for each clock output interface from the HPS component. For HPS-to-FPGA user clocks, specify the BFM clock rate in the **User clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Platform Designer (Standard).

The HPS-to-FPGA TPIU generates a clock output to the FPGA, named `h2f_tpiu_clock`. In simulation, the clock source BFM also represents this clock output's behavior. Also, the HPS-to-FPGA debug APB interface generates a clock output to the FPGA, named `h2f_debug_apb_clock`.

Table 30-13: HPS Clock Output Interface Simulation Model

The Intel clock source BFM application programming interface (API) applies to all the BFM's listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
<code>h2f_user0_clock</code>	<code>h2f_user0_clock_inst</code>
<code>h2f_user1_clock</code>	<code>h2f_user1_clock_inst</code>
<code>h2f_user2_clock</code>	<code>h2f_user2_clock_inst</code>
<code>h2f_tpiu_clock</code>	<code>h2f_tpiu_clock_inst</code>

<code>h2f_warm_reset_handshake</code>	<code>h2f_warm_reset_handshake_inst</code>	<code>set_h2f_pending_rst_req_n()</code> <code>get_f2h_pending_rst_ack_n()</code>

Table 30-15: HPS Reset Output Interface Simulation Model

The reset source BFM application programming interface applies to all the BFM's listed.

Interface Name	BFM Instance Name
<code>h2f_reset</code>	<code>h2f_reset_inst</code>
<code>h2f_cold_reset</code>	<code>h2f_cold_reset_inst</code>
<code>h2f_debug_apb_reset</code>	<code>h2f_debug_apb_reset_inst</code>

Table 30-16: Configuration of Reset Source BFM for HPS Reset Output Interface

The HPS reset output interface is connected to a reset source BFM. Platform Designer (Standard) configures the BFM as shown in the following table. The parameter value of the instantiated BFM is configured for HPS simulation.

Parameter	BFM Value	Meaning
Assert reset high	Off	This parameter is off, specifying an active-low reset signal from the BFM.
Cycles of initial reset	0	This parameter is 0, specifying that the BFM does not assert the reset signal automatically.

FPGA-to-HPS SDRAM Interface

The HPS component contains a memory interface simulation model to which all of the FPGA-to-HPS SDRAM interfaces are connected. The model is based on the HPS implementation and provides cycle-level accuracy, reflecting the true bandwidth and latency of the interface. However, the model does not have the detailed configuration provided by the HPS software, and hence does not reflect any inter-port scheduling that might occur under contention on the real hardware when different priorities or weights are used.

Related Information

Functional Description—Hard Memory Interface

For more information, refer to “EMI-Related HPS Features in SoC Devices” in the *Functional Description—Hard Memory Interface* chapter in volume 3 of the *External Memory Interface Handbook*.

HPS Memory Interface Simulation

The HPS component provides a complete simulation model of the HPS memory interface controller and PHY, with cycle-level accuracy, comparable to the simulation models for the FPGA memory interface.

There are three simulation modes:

- Skip-cal - In the simulation, the memory comes up already calibrated.
- Quick-cal - The calibration process is sped up so that you do not have to wait so long into the simulation to start reading or writing memory.
- Full-cal - The entire calibration sequence is simulated. This means that you will be waiting a while before the memory controller is online.

The simulation model supports only the skip-cal simulation mode. Quick-cal and full-cal are not supported. Although an example design is not provided, you can create a test design by adding the traffic generator component to your design using Platform Designer (Standard). Also, the HPS simulation model does not use external memory pins to connect to the DDR memory model; instead, the memory model is incorporated directly into the HPS SDRAM interface simulation modules.

One of the various ways you can simulate the FPGA-to-SDRAM interfaces is by:

- Bring the interfaces out of reset; otherwise, transactions cannot occur.
- Connect the H2F reset to the F2H port resets.
- Add a stage to your testbench to assert and deassert the H2F reset in the HPS.

The appropriate Verilog code is shown below:

```
Initial
begin
  // Assert reset
  <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_assert();
  // Delay
  #1
  // Deassert reset
  <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_deassert();
end
```

HPS-to-FPGA MPU Event Interface

The HPS-to-FPGA MPU event interface is connected to a conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 30-20: HPS-to-FPGA MPU Event Interface Simulation Model

The usage of conduit `get_*`() and `set_*`() API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

The Intel system-on-a-chip (SoC) device provides a variety of ways to boot the hard processor system (HPS) and configure the FPGA portion.

Boot Overview

The boot flow of the HPS is a multi-stage process. Each stage is responsible for loading the next stage.

The first software stage is the boot ROM. The boot ROM code locates and executes the second software stage, called the preloader. The preloader locates, and if present, executes the next software stage. The preloader and subsequent software stages (if present) are collectively referred to as user software.

Only the boot ROM code is located in the HPS. Subsequent software is located external to the HPS and is provided by users. The boot ROM code is only aware of the preloader and not aware of any potential subsequent software stages.

The figure below illustrates the typical boot flow. However, there may be more or less software stages in the user software than shown and the roles of the software stages may vary.

Figure A-1: Typical Boot Flow

FPGA Configuration Overview

After power is applied to the FPGA and HPS portion of the SoC, configuration may begin. The FPGA may be configured through a variety of ways, such as through the HPS, JTAG, or an external host.

The control block (CB) in the FPGA portion of the device is responsible for obtaining an FPGA configuration image and configuring the FPGA. The FPGA configuration ends when the configuration image has been fully loaded and the FPGA enters user mode. The FPGA configuration image is provided by users and is typically stored in external non-volatile flash-based memory. The FPGA CB can obtain a configura-

tion image from the HPS through the FPGA manager or from any of the sources supported by the Cyclone V FPGA family.

Related Information

- [FPGA Manager](#) on page 5-1
For more information regarding programming the FPGA through the HPS, refer to the *FPGA Manager* chapter.

Booting and Configuration Options

SoC initialization includes the booting of the HPS and the configuration of the FPGA fabric and I/O.

Depending on the initialization option you choose, the I/O configuration is handled differently. You can choose one of the three initialization options:

- The HPS boot and FPGA configuration occur separately.
- The HPS boots first and then configures the FPGA.
- The HPS boots from the FPGA after the FPGA is configured.

Note: The HPS and FPGA fabric must be powered at the same time. You must not power-down the HPS or FPGA independently in the middle of device operation.

The following three figures illustrate the possible HPS boot and FPGA configuration schemes. The arrows in the figures denote the data flow direction.

Figure A-2: Separate FPGA Configuration and HPS Booting

In the figure below, the FPGA configuration and HPS boot can occur independently. The FPGA obtains its configuration image from a non-HPS source, while the HPS boot ROM obtains its preloader from a non-FPGA fabric source.

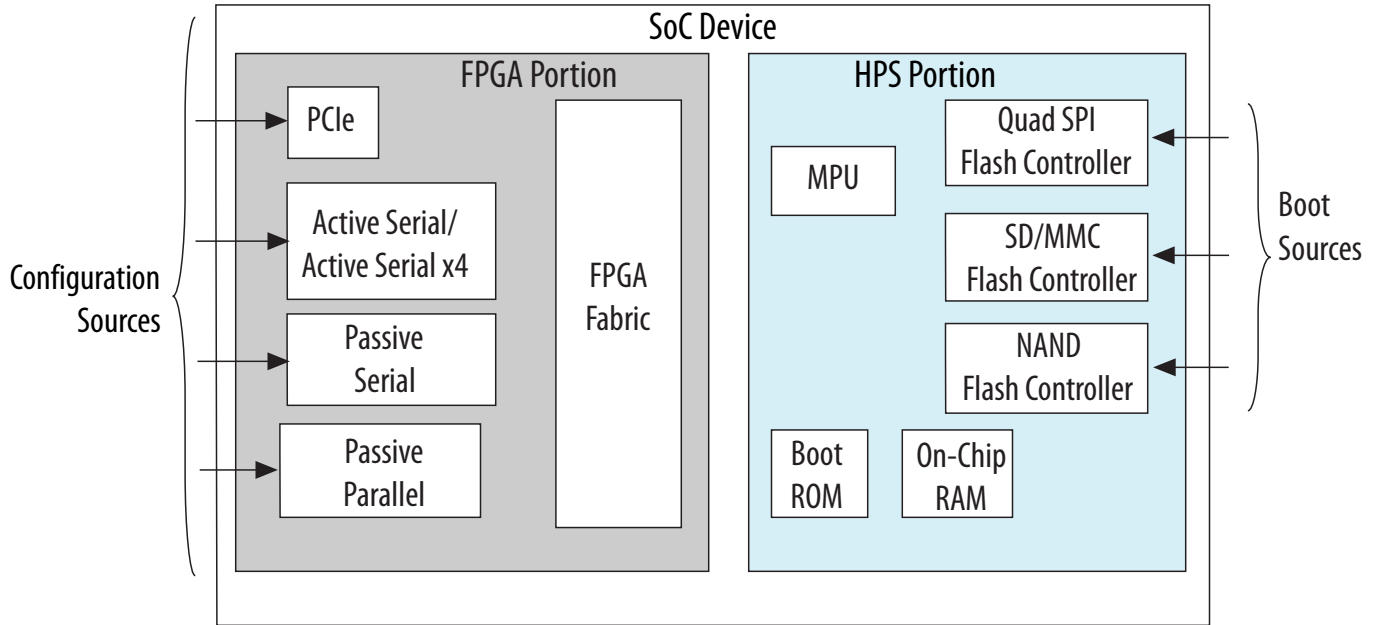

Figure A-3: HPS Boots First and then Configures the FPGA

In the figure below, the HPS boots first through one of its non-FPGA fabric boot sources. The FPGA does not need to be configured in order for the HPS to boot. However, the FPGA must be in a power-on state for the HPS to reset properly. The software on the HPS obtains the FPGA configuration image from any of its flash memory devices or communication interfaces, for example, the Ethernet media access controller (EMAC).

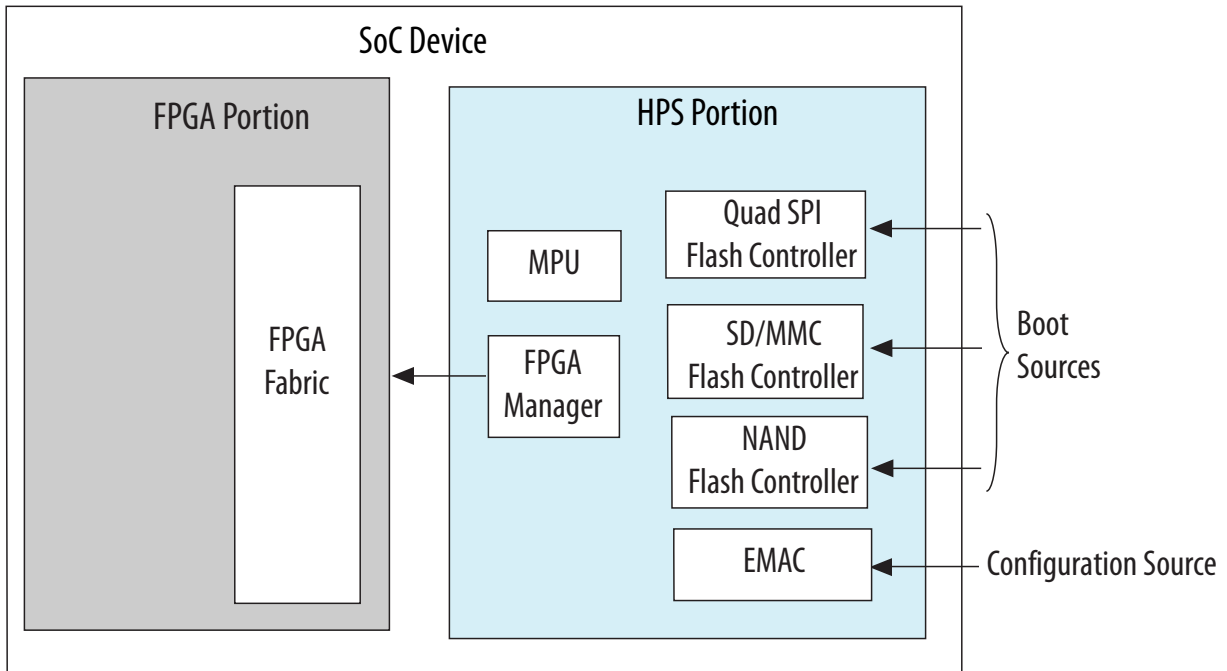

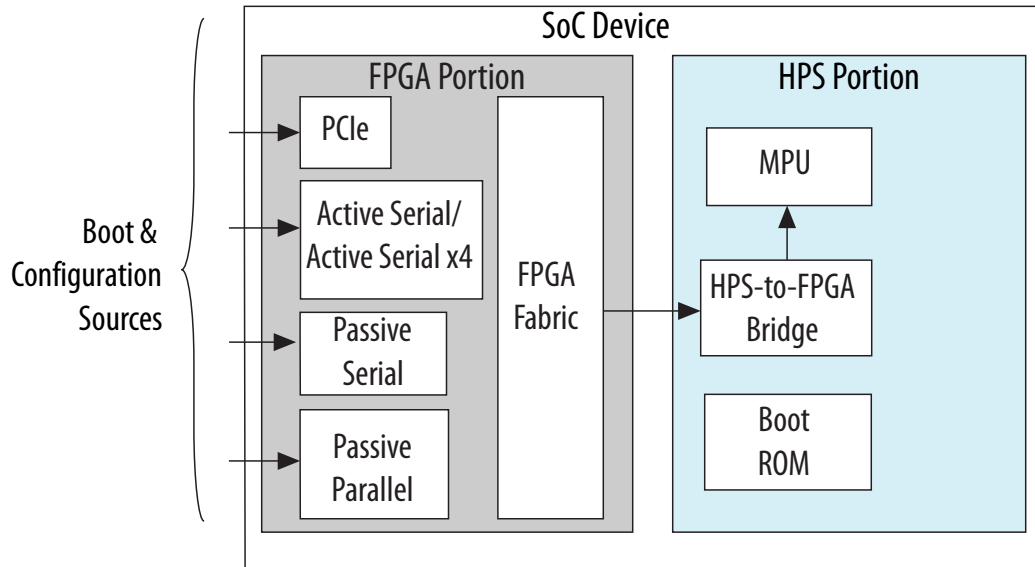

Figure A-4: HPS Boots From FPGA

In the figure below, the FPGA is configured first through one of its non-HPS configuration sources and then the HPS executes the preloader from the FPGA. In this situation, the HPS should not be released from reset until the FPGA is powered on and programmed. Once the FPGA is in user mode and the HPS has been released from reset, the boot ROM code begins executing. The HPS boot ROM code executes the preloader from the FPGA fabric over the HPS-to-FPGA bridge.

Boot Definitions

The following sections contain basic terms and definitions that are part of the boot process.

Reset

Reset precedes the boot stages and is an important part of device initialization. There are two different reset types: cold reset and warm reset.

The boot process begins when the CPU in the MPU exits from the reset state. When the CPU exits from reset, it starts executing code at the reset exception address where the boot ROM code is located.

With warm reset, some software registers are preserved and the boot process may skip some steps depending on software settings. In addition, on a warm reset, the preloader has the ability to be executed from on-chip RAM.

Boot ROM

The boot ROM code is 64 KB in size and located in on-chip ROM at address range 0xFFFD0000 to 0xFFDFFFFF. The function of the boot ROM code is to determine the boot source, initialize the HPS after a reset, and jump to the preloader. In the case of indirect execution, the boot ROM code loads the

preloader image from the flash memory to on-chip RAM. The boot ROM performs the following actions to initialize the HPS:

- Enable instruction cache, branch predictor, floating point unit, NEON vector unit of CPU0
- Sets up the level 4 (L4) watchdog timer
- Configures the main PLL and peripheral PLL based on the CSEL value
- Initializes the flash controller to default settings

When booting from flash memory, the boot ROM code uses the top 4 KB of the on-chip RAM as data workspace. This area is reserved for the boot ROM code after a reset until the boot ROM code passes software control to preloader. For a warm RAM boot or a cold boot from FPGA, the boot ROM code does not reserve the top 4 KB of the on-chip RAM, and the user may place user data in this area without being overwritten by boot ROM.

The boot process begins when CPU0 exits from the reset state. The boot ROM code only executes on CPU0. CPU1 is held in reset while boot ROM executes on CPU0. When a CPU0 exits from reset, it starts executing code at the reset exception address.

When CPU0 exits the boot ROM code and starts executing user software, the boot ROM access is disabled. The user software in CPU0 must map the user software exception vectors at 0x0 (which is previously mapped to boot ROM exception vectors). The user software also has the option of releasing CPU1 from reset. If CPU1 is released from reset, CPU1 executes the user software exception instead of boot ROM.

Boot Select

The boot select (BSEL) pins offer multiple methods to obtain the preloader image. On a cold reset or when a RAM boot has not been requested, the user asserts the BSEL pins on the device to indicate the boot source that is required. These pins are sampled on deassertion of cold reset and are written to the `bootinfo` register in the System Manager. The value of this register is read during boot ROM execution so that the appropriate interface pins can be initialized. If the boot source is from FPGA, the `bse1` field value reads as 0x1 in the `bootinfo` register and no HPS interface is configured for external boot.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Table A-1: BSEL Values for Boot Source Selection

BSEL[2:0] Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.3 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.3 V SD/MMC flash memory with internal transceiver

BSEL[2:0] Value	Flash Device
0x6	1.8 V quad SPI flash memory
0x7	3.3 V quad SPI flash memory

Note: If the BSEL value is set to 0x4 or 0x5, an external translation transceiver may be required to supply level-shifting and isolation if the SD cards interfacing to the SD/MMC controller must operate at a different voltage than the controller interface. Please refer to the *SD/MMC Controller* chapter for more information.

The HPS flash sources can store various file types, such as:

- FPGA programming files
- Preloader binary file (up to four copies)
- Boot loader binary file
- Operating system binary files
- Application file system

When BSEL = 0x1, the boot source is the FPGA and the CSEL pins are ignored. PLLs are bypassed so that OSC1 drives all the clocks.

If an HPS flash interface has been selected to load the boot image, then the boot ROM enables and configures that interface before loading the boot image into on-chip RAM, verifying it and passing software control to the preloader.

If the external RAM boot source is invalid or if the boot ROM code cannot find a valid image in flash, then the boot ROM code checks to see if there is a fallback image in the FPGA. If there is then the boot ROM executes that.

If the FPGA fabric is the boot source, the boot ROM code waits until the FPGA portion of the device is in user mode, and is ready to execute code and then passes software control to the preloader in the FPGA RAM.

Flash Memory Devices for Booting

The memory controllers and devices that contain the boot loader image have configuration requirements for proper boot from flash.

SD/MMC Flash Devices

The following figure shows an SD/MMC flash image layout example for boot. The master boot record (MBR) is located in the first 512 bytes of the memory. The MBR contains information about the partitions (address and size of partition). The preloader image is stored in partition A2. Partition A2 is a custom raw partition with no file system.

Figure A-5: SD/MMC Flash Image Layout

The SD/MMC controller supports two booting modes:

- MBR (partition) mode
 - The boot image is read from a custom partition (0xA2)
 - The first image is located at the beginning of the partition, at offset 0x0
 - Start address = partition start address
- Raw mode
 - If the MBR signature is not found, SD/MMC driver assumes it is in raw mode
 - The boot image data is read directly from sectors in the user area and is located at the first sector of the SD/MMC
 - The first image is located at the start of the memory card, at offset 0x0
 - Start address = 0x0

The MBR contains the partition table, which is always located in the first sector (LBA0) with a memory size of 512 bytes. The MBR consists of executable code, four partition entries, and the MBR signature. A MBR can be created by specific tools like the FDISK program.

Table A-9: MBR Structure

Offset	Size (In Bytes)	Description
0x000	446	Code area
0x1BE	16	Partition entry for partition 1
0x1CE	16	Partition entry for partition 2
0x1DE	16	Partition entry for partition 3
0x1EE	16	Partition entry for partition 4
0x1FE	2	MBR signature: 0xAA55

The standard MBR structure contains a partition with four 16-byte entries. Thus, memory cards using this standard table cannot have more than four primary partitions or up to three primary partitions and one extended partition.

Each partition type is defined by the partition entry. The boot images are stored in a primary partition with custom partition type (0xA2). The SD/MMC flash driver does not support a file system, so the boot images are located in partition A2 at fixed locations.

Table A-10: Partition Entry

Offset	Size (In Bytes)	Description
0x0	1	Boot indicator. 0x80 indicates that it is bootable.
0x1	3	Starting CHS value
0x4	1	Partition type
0x5	3	Ending CHS value
0x8	4	LBA of first sector in partition
0xB	4	Number of sectors in partition

The boot ROM code configures the SD/MMC controller to default settings for the supported SD/MMC flash memory.

Refer to the *SD/MMC Controller* chapter for more information regarding features and functionality.

Default Settings of the SD/MMC Controller

Table A-11: SD/MMC Controller Default Settings

Parameter	Default	Register Value
Card type	1 bit	The card type register (<code>ctype</code>) in the SD/MMC controller registers (<code>sdmmc</code>) = 0x0
Bus mode	—	SD/MMC ⁽⁷¹⁾
Timeout	Maximum	The timeout register (<code>tmout</code>) = 0xFFFFFFFF
FIFO threshold RX watermark level	1	The RX watermark level field (<code>rx_wmark</code>) of the FIFO threshold watermark register (<code>fifoth</code>) = 0x1

⁽⁷¹⁾ SPI cards are not supported for boot.

Parameter		Default	Register Value
Clock source		0	The clock source register (<code>clksrc</code>) = 0x0
Block size		512	The block size register (<code>blksiz</code>) = 0x200
Clock divider	Identification mode	32	The clock divider register (<code>clkdiv</code>) = 0x10 ($2 \times 16 = 32$)
	Data transfer mode	Bypass	The clock divider register (<code>clkdiv</code>) = 0x00
External Device Power enable		Disabled (Power Off)	<p>The <code>power_enable</code> bit in the <code>pwren</code> register is programmed to 0x0 out of reset, meaning the <code>sdmmc_pwren</code> signal is not active and does not do anything at boot time. A pull-up should be attached to the <code>sdmmc_pwren</code> pin for proper functionality.</p> <p>Note: If the SD/MMC controller is used as the boot source, then power to the corresponding SD card must be supplied from a power controller on the board. After boot has completed and the SD/MMC controller has been fully configured, the <code>sdmmc_pwren</code> signal can be used to turn on and off the SD card through the <code>pwren</code> register.</p>

CSEL Settings for the SD/MMC Controller

Table A-12: SD/MMC Controller CSEL Pin Settings

Setting		CSEL[1:0] Pin Value			
		0	1	2	3
osc1_clk (HPS1_CLK pin) range		10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz
ID mode	Device clock (sdmmc_cclk_out)	osc1_clk/512, 97.66 KHz max	osc1_clk/128, 97.66 KHz max	osc1_clk/256, 97.66 KHz max	osc1_clk/512, 97.66 KHz max
	Controller baud rate divisor	32	32	32	32
Data transfer mode	Device clock (sdmmc_cclk_out)	osc1_clk/4, 12.5 MHz max	osc1_clk*1, 12.5 MHz max	osc1_clk/2, 12.5 MHz max	osc1_clk/4, 12.5 MHz max
	Controller baud rate divisor (even numbers only)	1 (bypass)	1 (bypass)	1 (bypass)	1 (bypass)
Controller clock (sdmmc_clk)		osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk, 50 MHz max
mpu_clk		osc1_clk, 50 MHz max	osc1_clk*32, 400 MHz max	osc1_clk*16, 400 MHz max	osc1_clk*8, 400 MHz max
PLL modes		Bypassed	Locked	Locked	Locked

NAND Flash Devices

The NAND subsystem reserves at least the first 256 KB on the NAND device. If the NAND flash device has blocks greater than 64 KB, then the NAND subsystem reserves the first four blocks on the device. For a NAND device with less than 64 KB block size, the preloader image must be placed in multiple blocks. The NAND subsystem expects to find up to four preloader images on the NAND device. You may have less than four if required. The preloader image should always be at the start of a physical page. Because a block is the smallest area used for erase operation, any update to a particular image does not affect other images.

NAND Flash Driver Features Supported in the Boot ROM Code

Table A-13: NAND Flash Support Features

Feature	Driver Support
Device	Open NAND Flash Interface (ONFI) 1.0 raw NAND or electronic signature devices, single layer cell (SLC) and multiple layer cell (MLC)
Chip select	CS0 only. Only CS0 is available to the HPS, the other three chip selects are routed out to the FPGA portion of the device
Bus width	8-bit only
Page size	512 bytes, 2 KB, 4 KB, or 8 KB
Page per block	32, 64, 128, 384 and 512
ECC	512-bytes with 8-bit correction

CSEL Settings for the NAND Controller

Table A-14: NAND Controller CSEL Pin Settings

Setting	CSEL[1:0] Pin Value			
	0	1	2	3
osc1_clk (HPS1_CLK pin) range	10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz
Device frequency (nand_x_clk/4)	osc1_clk/4, 12.5 MHz max	osc1_clk*8/4, 25 MHz max	osc1_clk*4/4, 25 MHz max	osc1_clk2/4, 25 MHz max
Controller clock (nand_x_clk)	osc1_clk, 50 MHz max	osc1_clk*8, 100 MHz max	osc1_clk*4, 100 MHz max	osc1_clk*2, 100 MHz max
mpu_clk	osc1_clk, 50 MHz max	osc1_clk*32, 400 MHz max	osc1_clk*16, 400 MHz max	osc1_clk*8, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

Quad SPI Flash Devices

The figure below shows the quad SPI flash image layout. The preloader image is always located at offsets that are multiples of 64 KB.

Figure A-9: Quad SPI Flash Image Layout

The boot ROM code configures the quad SPI controller to default settings for the supported SPI or quad SPI flash memory.

Related Information

[Quad SPI Flash Controller](#) on page 16-1

Refer to the *Quad SPI Flash Controller* chapter for more information regarding features and functionality.

Quad SPI Controller Default Settings

Table A-15: Quad SPI Controller Default Settings

Parameter	Default Setting	Register Value
SPI baud rate	Divide by 4	The master mode baud rate divisor field (<code>bauddiv</code>) of the quad SPI configuration register (<code>cfg</code>) in the quad SPI controller registers (<code>qspregs</code>) = 1.
Read opcode	CSEL = 0 or 1: Normal read CSEL = 2 or 3: Fast read	The read opcode in non-XIP mode field (<code>rdopcode</code>) in the device read instruction register (<code>devrd</code>) = 0x3 (for normal read) and 0xB (for fast read).
Instruction type	Single I/O (1 bit wide)	The address transfer width field (<code>addrwidth</code>) and data transfer width field (<code>datawidth</code>) of the <code>devrd</code> register = 0.
Number of address bytes	3 bytes	The number of address bytes field (<code>numaddrbytes</code>) of the device size register (<code>devsz</code>) = 2. Note: Before a reset, you must ensure that the QSPI flash device is configured to 3 byte address mode for the boot ROM to function properly.

Parameter	Default Setting	Register Value
Delay in terms of <code>qspi_ref_clk</code> clock cycles for the length that the master mode chip select outputs are deasserted between words when the clock phase is zero	The default setting in clock cycles must equal 200 ns	The clock delay for chip select deassert (field <code>nss</code> in the quad SPI device delay register (<code>delay</code>)). Refer to <code>delay[31:24]</code> in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Delay in terms of <code>qspi_ref_clk</code> clock cycles between one chip select being deactivated and the activation of another. This delay ensures a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty	The default setting is 0 clock cycles.	The clock delay for chip select deactivation (field <code>btwn</code> in the <code>delay</code> register = 0x0).
Delay in terms of <code>qspi_ref_clk</code> clock cycles between the last bit of the current transaction and the first bit of the next transaction. If the clock phase is zero, the first bit of the next transaction refers to the cycle in which the chip select is deselected	The default setting in clock cycles must equal 20 ns.	The clock delay for last transaction bit (field <code>after</code> in the <code>delay</code> register). Refer to <code>delay[15:8]</code> in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Added delay in terms of <code>qspi_ref_clk</code> clock cycles between setting <code>qspi_n_ss_out</code> low and first bit transfer	The default setting in clock cycles must equal 20 ns.	The clock delay of <code>qspi_n_ss_out</code> (field <code>init</code> in the <code>delay</code> register). Refer to <code>delay[7:0]</code> in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.

Quad SPI Flash Delay Configuration

The `delay` register in the quad SPI controller configures relative delay of the generation of the master output signals. All timings are defined in cycles of `qspi_ref_clk`.

The quad SPI flash memory must meet the following timing requirements:

- T_{SLCH} : 20 ns
 - T_{SLCH} is used to calculate the `init` field (`delay[7:0]`) in the `delay` register. The `init` field represents the delay in `qspi_ref_clk` clocks between pulling the device chip select (`qspi_n_ss_out`) low and the first bit transfer.
- T_{CHSH} : 20 ns
 - T_{CHSH} is used to calculate the `after` field (`delay[15:8]`) in the `delay` register. The `after` field represents the delay in the `qspi_ref_clk` clocks between last bit of the current transaction and the deassertion of the device chip select (`qspi_n_ss_out`).
- T_{SHSL} : 200 ns
 - T_{SHSL} is used to calculate the `nss` field (`delay[31:24]`) in the `delay` register and is the delay in the `qspi_ref_clk` clocks for the length that the master mode chip select outputs are deasserted between transactions.
- $T_{qspi_ref_clk}$ is the master reference clock/external clock, `qspi_ref_clk`.

The formulas to calculate the fields in the `delay` register are:

$$\text{delay}[7:0] = \text{init} = T_{SLCH} / T_{qspi_ref_clk}$$

$$\text{delay}[15:8] = \text{after} = T_{CHSH} / T_{qspi_ref_clk}$$

$$\text{delay}[31:24] = \text{nss} = (T_{SHSL} - T_{qspi_clk}) / T_{qspi_ref_clk}$$

Table A-16: Quad SPI Flash Delay Configuration

CSEL[1:0] Pin Value	$T_{qspi_ref_clk}$ (ns)	T_{qspi_clk} (ns)	Device Delay Register		
			delay[7:0] (init)	delay[15:8] (after)	delay[31:24] (nss)
0	20	80	1	1	6
1	10	40	2	2	16
2-3	5	20	4	4	36

Read data capture delay is also configured when booting from QSPI. Depending on the `CSEL` pin settings, the Boot ROM configures the `delay` field of the `rddatacap` register in the QSPI differently. When `CSEL Pins[1:0]=0x0` or `0x1`, the Boot ROM leaves the `delay` field in the `rddatacap` register untouched. When `CSEL Pins[1:0]=0x2` or `0x3`, the boot ROM calibrates the interface by reading the QSPI signal for all delay values of the `rddatacap` register. The Boot ROM analyzes all of the delay values that return a valid signature and uses the delay value in the middle of the valid window as the value it programs into the `delay` field of the `rddatacap` register.

Quad SPI Controller CSEL Settings

Table A-17: Quad SPI Controller CSEL Pin Settings

Setting	CSEL[1:0] Pin Value			
	0 ⁽⁷²⁾	1	2	3
osc1_clk (HPS1_CLK pin) range	10–50 MHz	20–50 MHz	25–50 MHz	10–25 MHz
Device clock (qspi_clk)	osc1_clk/4, 12.5 MHz max	osc1_clk/2, 25 MHz max	osc1_clk*1, 50 MHz max	osc1_clk*2, 50 MHz max
Controller clock (qspi_ref_clk)	osc1_clk, 50 MHz max	osc1_clk*2, 100 MHz max	osc1_clk*4, 200 MHz max	osc1_clk*8, 200 MHz max
Controller baud rate divisor (even numbers only)	4	4	4	4
Flash read instruction (1 dummy byte for READ_FAST)	READ	READ	READ_FAST	READ_FAST
mpu_clk	osc1_clk, 50 MHz max	osc1_clk*8, 400 MHz max	osc1_clk*8, 400 MHz max	osc1_clk*16, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

Clock Select

The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

The clock select (CSEL) pins are asserted to select the speed of the HPS boot interface. If the FPGA is used as the boot source, the CSEL pins are ignored. The CSEL values define the main PLL, 12_mp_clk and 14_sp_clk. Based on the clock source and clock select settings, boot ROM configures the main PLL and peripheral PLL parameters and the clock dividers for clocks derived from the PLLs.

Note: The terms CSEL and CLKSEL are used interchangeably in Intel documentation to refer to clock select.

Note: At power-up or reset, when CSEL[1:0]=0x0 or BSEL[2:0] is configured to boot from FPGA, the HPS PLLs are in bypass mode. Thus, HPS user clocks exported to the FPGA fabric run at osc1_clk frequency.

I/O Configuration

The flash devices needed for booting must be connected to specific I/Os. The Boot ROM configures these I/Os depending on the flash device selected by boot select setting. To configure the I/Os, the boot ROM performs pin muxing and pin configuration on these I/Os.

At power up, the dedicated I/O are in tri-state with a weak pull-up until the Boot ROM or preloader configures the I/O. On cold reset, the boot ROM always configures the pin muxes and pin configurations.

⁽⁷²⁾ Not applicable when on WARM reset.

On warm reset, the user has the capability to specify whether or not the boot ROM code configures the I/Os and pin muxes for boot pins after a warm reset. This configuration on warm reset is enabled by programming the `ctrl` register in the Boot ROM Code Register group of the System Manager.

L4 Watchdog 0 Timer

The boot ROM enables the L4 Watchdog 0 Timer early in the boot process.

This watchdog is reserved for the boot ROM until the preloader indicates that it has started correctly and taken control of the exception vectors. The timeout is at least one second, depending on the clock select setting. Because the watchdog is reset just before the control passes to preloader, the preloader must reset the watchdog when it begins execution.

The L4 watchdog 0 timer is reserved for boot ROM use. While booting, if a watchdog reset happens before software control passes to the preloader, the boot ROM code attempts to load the last valid preloader image, identified by the `initswlastld` register in the System Manager.

If the watchdog reset happens after the preloader has started executing but before it writes a valid value to `initswstate` register, the boot ROM increments `initswlastld` and attempts to load that image. If the watchdog reset happens after the preloader writes a valid value to `initswstate` register, the boot ROM code attempts to load the image indicated by `initswlastld` register.

Preloader

The function of the preloader is user-defined. However, typical functions include:

- Initializing the SDRAM interface
- Configuring the HPS I/O pins
- Initializing the interface that loads the next stage of software

Initializing the SDRAM allows the preloader to load the next stage of the boot software (that might not fit in the 60 KB available in the on-chip RAM) into SDRAM. A typical next software stage is the open source boot loader, U-boot. The preloader is allowed to load the next boot software stage from any device available to the HPS. Typical sources include the same flash device that contains the preloader, a different flash device, or a communication interface such as an EMAC.

U-Boot Loader

The optional U-boot loader loads the operating system and passes software control to the operating system.

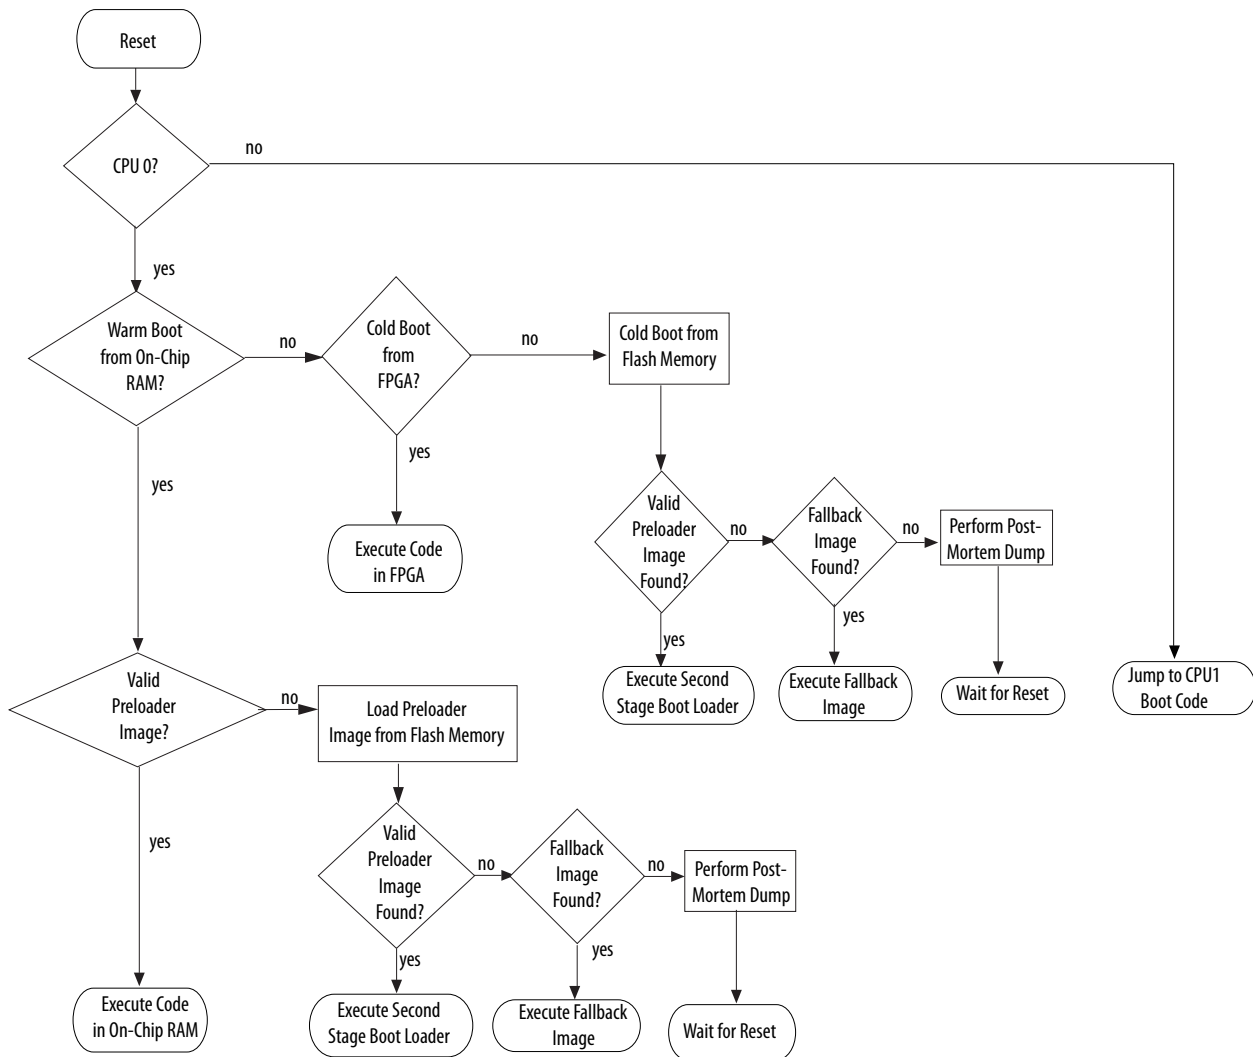

Boot ROM Flow

On a cold reset, the HPS boot process starts when CPU0 is released from reset (for example, on a power up) and executes code in the internal boot ROM at the reset exception address. The boot ROM code brings the SoC out of reset and into a known state. After boot ROM code is exited, control passes to the next stage of the boot software, referred to as the preloader. The preloader can be customized and is typically stored external to the HPS in a nonvolatile flash-based memory or in on-chip RAM within the FPGA. Beyond that, another boot layer can be executed before loading the operating system software.

This section describes the software flow from reset until the boot ROM code passes software control to the preloader.

The following figure illustrates that the boot ROM code can perform a warm boot from on-chip RAM, a cold boot from the FPGA portion of the device, or a cold boot from flash memory.

Figure A-10: BOOT ROM FLOW

After a reset, the boot ROM code determines which CPU it is executing on. If it is executing on CPU 1, then control is passed to CPU1 and the boot ROM execution is complete. This event only happens if the user code releases CPU1 without resetting the exception vectors.

If the boot ROM is executing on CPU0, it checks to see if an on-chip RAM boot is requested. An on-chip RAM boot can only occur on a warm reset. Warm boot from on-chip RAM has the highest priority to execute if the `warmramgrp` registers in the `romcodegrp` group in the system manager has been configured to support booting from on-chip RAM on a warm reset. If the `enable` register in the System Manager is set to `0xAE9EFEB`, then the boot ROM code will attempt to boot from on-chip RAM on a warm reset and the boot ROM will not configure boot I/Os, pin-muxes or clocks. The `datastart` and `length` registers in System Manager allow you to program the offset of the beginning of code and the length of the region

of on-chip RAM for CRC validation. If the `length` register is clear, then boot ROM will not perform a CRC calculation on the on-chip RAM.

If a valid preloader image cannot be found in the on-chip RAM, or the preloader in the on-chip RAM fails the CRC check, the boot ROM code attempts to load the last valid preloader image loaded from the flash memory, identified by the `index` field of the initial software last image loaded register (`initswlastld`) in the `romcodegrp` group in the system manager. If the image is invalid, boot ROM code attempts to load up to three subsequent images from flash memory. If a valid preloader image cannot be found in the on-chip RAM or flash memory, the boot ROM code checks the FPGA portion of the device for a fallback image.

If the warm RAM boot has failed or if a cold reset has occurred, then the boot ROM reads the BSEL value in the `bootinfo` register of the System Manager. If the FPGA is selected as the boot source, then the boot ROM code attempts to execute code at address `0xC0000000` across the HPS-to-FPGA bridge (offset `0x00000000` from bridge). No error conditions are generated if the FPGA does not initialize properly and the watchdog is not enabled for time-out. Instead, the boot ROM continues to wait until the FPGA is available.

If the BSEL bits indicate a boot from external flash, then the boot ROM code attempts to load an image from a flash device into the on-chip RAM, verify and execute it. If the BSEL is invalid or the boot ROM code cannot find a valid image in the flash, then the boot ROM code checks if there is a fallback image in the FPGA. If there is, then the boot ROM executes the fallback image. If there is no fallback image then the boot ROM performs a post-mortem dump of information into the on-chip RAM and awaits a reset.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Typical Preloader Boot Flow

This section describes a typical software flow from the preloader entry point until the software passes control to the next stage boot software.

Figure A-11: Typical Preloader Flow

Low-level initialization steps include reconfiguring or disabling the L4 watchdog 0 timer, invalidating the instruction cache and branch predictor, remapping the on-chip RAM to the lowest memory region, and setting up the data area.

Upon entering the preloader, the L4 watchdog 0 timer is active. The preloader can disable, reconfigure, or leave the watchdog timer unchanged. Once enabled after reset, the watchdog timer cannot be disabled, only paused.

The instruction cache and branch predictor, which were previously enabled by the boot ROM code, need to be invalidated.

HPS State on Entry to the Preloader

When the boot ROM code is ready to pass control to the preloader, the processor (CPU0) is in the following state:

- Instruction cache is enabled
- Branch predictor is enabled
- Data cache is disabled
- MMU is disabled
- Floating point unit is enabled
- NEON vector unit is enabled
- Processor is in Arm secure supervisor mode

The boot ROM code sets the Arm Cortex-A9 MPCore registers to the following values:

- r0—contains the pointer to the shared memory block, which is used to pass information from the boot ROM code to the preloader. The shared memory block is located in the top 4 KB of on-chip RAM.
- r1—contains the length of the shared memory.
- r2—unused and set to 0x0.
- r3—reserved.

All other MPCore registers are undefined.

Note: When booting CPU0 using the FPGA boot, or when booting CPU1 using any boot source, all MPCore registers, caches, the MMU, the floating point unit, and the NEON vector unit are undefined. HPS subsystems and the PLLs are undefined.

When the boot ROM code passes control to the preloader, the following conditions also exist:

- The boot ROM is still mapped to address 0x0.
- The L4 watchdog 0 timer is active and has been toggled.

The boot ROM also saves the state of the reset cause in the `stat` register of the Reset Manager and this information is available for the preloader to read.

Shared Memory

The shared memory contains information that the boot ROM code passes to the preloader. The boot ROM code passes the location of shared memory to the preloader in register `r0`, as described in the *HPS State on Entry to Preloader* section.

The shared memory holds the last value of the `stat` register in the Reset Manager Module and a version number that is passed by the boot ROM. The value of the `stat` register in shared memory is only valid if the version number passed by the boot ROM is 0x00000000. The table below shows where the `stat` register value and version number reside in the shared memory as an offset from the address stored in register `r0`.

Table A-18: Shared Memory Locations

Shared Memory Content	Address Location	Description
Version Number	$r0 + 0x0008$	The <i>stat</i> register value in shared memory is only valid if the value of this shared memory location is 0x00000000.
<i>stat</i> Register	$r0 + 0x0038$	This location holds the last value the boot ROM writes to the <i>stat</i> register in the Reset Manager before it is erased.

Loading the Preloader Image

The boot ROM code loads the image from flash memory into the on-chip RAM and passes control to the preloader. The boot ROM code checks for a valid image by verifying the header and cyclic redundancy check (CRC) in the preloader image.

The boot ROM code checks the header for the following information:

- Validation word—validates the preloader image. The validation word has a fixed value of 0x31305341.
- Version—indicates the header version.
- Program length—the total length of the image (in 32-bit words) from offset 0x0 to the end of code area, including exception vectors and CRC.
- Checksum—a checksum of all the bytes in the header, from offset 0x40 to 0x49.

The preloader image has a maximum size of 60 KB. This size is limited by the on-chip RAM size of 64 KB, where 4 KB is reserved as a workspace for the boot ROM data and stack. The preloader can use this 4 KB region (for its stack and data, for example) after the boot ROM code passes control to the preloader. This 4 KB region is overwritten by the boot ROM code on a subsequent reset. The following figure shows the preloader image layout in the on-chip RAM after being loaded from the boot ROM.

Figure A-13: Preloader Image Layout

Exception vectors—Exception vectors are located at the start of the on-chip RAM. Typically, the second-stage boot loader remaps the lowest region of the memory map to the on-chip RAM (from the boot ROM) to create easier access to the exception vectors.

Header—contains information such as validation word, version, flags, program length, and checksum for the boot ROM code to validate the preloader boot loader image before passing control to the second-stage boot loader.

Entry point—After the boot ROM code validates the header, the boot ROM code jumps to this address.

User-defined code—typically contains the program code of the preloader.

CRC—contains a CRC of data from address 0xFFFF0000 to 0xFFFF0000+(Program Length*4)-0x0004. The polynomial used to validate the preloader image is:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

There is no reflection of the bits. The initial value of the remainder is 0xFFFFFFFF and the final value is XORed with 0xFFFFFFFF.

Reserved at reset—the top 4 KB is reserved for the boot ROM code after a reset. The boot ROM code uses this area for internal structures, workspace, and post-mortem dump. This area includes the shared memory where the boot ROM code passes information to the preloader.

FPGA Configuration

You can configure the FPGA portion of the SoC device with non-HPS sources or by utilizing the HPS.

When the HPS handles the initial FPGA configuration, software executing on the HPS writes the configuration image to the FPGA Manager in the HPS. Software can control the configuration process and monitor the FPGA status by accessing the control and status register (CSR) interface in the FPGA Manager.

Full Configuration

The HPS uses the FPGA manager to configure the FPGA portion of the device. The following sequence suggests one way for software to perform a full configuration:

- `CONF_DONE = 1` and `nSTATUS = 1` indicates successful configuration.
- `CONF_DONE = 0` or `nSTATUS = 0` indicates unsuccessful configuration. Complete steps 12 and 13, then go back and repeat steps 3 to 10 to reload the configuration image.
- If `DCLK` is unused, write a value of 4 to the `DCLK` count register (`dclkcnt`).
- If `DCLK` is used, write a value of 20,480 (0x5000) to the `dclkcnt` register.

If the HPS resets in the middle of a normal configuration data transfer before entering user mode, software can assume that the configuration is unsuccessful. After the HPS resets, software must repeat the steps for full configuration.

1. Set the `cdratio` and `cfgwidth` bits of the `ctrl` register in the FPGA manager registers (`fpgamgrregs`) to match the characteristics of the configuration image. These settings are dependent on the `MSEL` pins input.
2. Set the `nce` bit of the `ctrl` register to 0 to enable HPS configuration.
3. Set the `en` bit of the `ctrl` register to 1 to give the FPGA manager control of the configuration input signals.
4. Set the `nconfigpull` bit of the `ctrl` register to 1 to pull down the `nCONFIG` pin and put the FPGA portion of the device into the reset phase.
5. Poll the `mode` bit of the `stat` register and wait until the FPGA enters the reset phase.
6. Set the `nconfigpull` bit of the `ctrl` register to 0 to release the FPGA from reset.
7. Read the `mode` bit of the `stat` register and wait until the FPGA enters the configuration phase.
8. Clear the interrupt bit of `nSTATUS` (`ns`) in the `gpio interrupt` register (`fpgamgrregs.mon.gpio_porta_eoi`).
9. Set the `axicfggen` bit of the `ctrl` register to 1 to enable sending configuration data to the FPGA.
10. Write the configuration image to the configuration data register (`data`) in the FPGA manager module configuration data registers (`fpgamgrdata`). You can also choose to use a DMA controller to transfer the configuration image from a peripheral device to the FPGA manager.
11. Use the `fpgamgrregs.mon.gpio_ext_porta` registers to monitor the `CONF_DONE` (`cd`) and `nSTATUS` (`ns`) bits.
12. Set the `axicfggen` bit of the `ctrl` register to 0 to disable configuration data on AXI slave.
13. Clear any previous DONE status by writing a 1 to the `dcntdone` bit of the DCLK status register (`dclkstat`) to clear the completed status flag.
14. Send the DCLKs required by the FPGA to enter the initialization phase.
15. Poll the `dcntdone` bit of the DCLK status register (`dclkstat`) until it changes to 1, which indicates that all the DCLKs have been sent.
16. Write a 1 to the `dcntdone` bit of the DCLK status register to clear the completed status flag.
17. Read the `mode` bit of the `stat` register to wait for the FPGA to enter user mode.
18. Set the `en` bit of the `ctrl` register to 0 to allow the external pins to drive the configuration input signals.

Partial Reconfiguration

Partial reconfiguration allows you to reconfigure part of the device while other sections remain running. The HPS performs partial reconfiguration while the FPGA portion of the device is in user mode. The following sequence suggests one way for software to perform a partial configuration:

- If `PR_READY=1`, continue to step 7.
- If `PR_READY` is 0, then go back and repeat step 5. Note that a minimum of 16 DCLK pulses are required.

If the HPS resets in the middle of a partial reconfiguration, software can assume that the configuration is unsuccessful. After an HPS warm reset, software must repeat the steps for partial configuration. After an HPS cold reset, software must repeat the steps for [Full Configuration](#) on page 31-33.

1. Read the `mode` bit of the `stat` register in `fpgamgrregs` to ensure that the FPGA is in user mode.
2. Set the `cdratio` bit of the `ctrl` register to match the characteristics of the partial reconfiguration image and set the `cfgwidth` bit of the `ctrl` register to 0 for 16-bit configuration data width.
3. Set the `en` bit of the `ctrl` register to 1 to give the FPGA manager control of the configuration input signals.
4. Set the `prreq` bit of the `ctrl` register to 1 to assert `PR_REQUEST`.
5. Write a value of 1 to the `dclkcnt` register to generate `DCLK` pulses for one clock cycle.
6. Poll the `fpgamgrregs.mon` registers to observe the `PR_READY (prr)` bit.
7. Write a value of 3 to the `dclkcnt` register to generate `DCLK` pulses for three clock cycles.
8. Set the `axicfgen` bit of the `ctrl` register to 1 to enable sending configuration data to the FPGA.
9. Write the partial reconfiguration image to the `data` register in the FPGA manager `fpgamgrdata` registers. You can also choose to use a DMA to transfer the configuration image from a peripheral device to the FPGA manager.
10. Poll the `fpgamgrregs.mon` registers to observe the `PR_DONE (prd)`, `PR_READY (prr)`, `PR_ERROR (pre)`, and `CRC_ERROR (crc)` bits until the bits match one of the completion statuses shown in Table A-12.
11. Set the `axicfgen` bit of the `ctrl` register to 0 to disable sending configuration data to the FPGA.
12. Set the `prreq` bit of the `ctrl` register to 0 to deassert `PR_REQUEST`.
13. Write a value of 128 to the `dclkcnt` register to generate `DCLK` pulses for 128 clock cycles.
14. Poll the `dcntdone` bit of the `dclkstat` register until it changes to 1, which indicates that all the `DCLKs` have been sent.
15. Write a 1 to the `dcntdone` bit of the `dclkstat` register to clear the completed status flag.
16. Poll the `fpgamgrregs.mon` registers to observe the `PR_DONE (prd)`, `PR_READY (prr)`, `PR_ERROR (pre)`, and `CRC_ERROR (crc)` bits. When all bits are set to 0, the FPGA is ready for the next transaction.
17. Set the `en` bit of the `ctrl` register to 0 to allow the external pins to drive the configuration input signals.
