This chapter describes the direct memory access controller (DMAC) contained in the hard processor system (HPS). The DMAC transfers data between memory and peripherals and other memory locations in the system. The DMA controller is an instance of the Arm CoreLink DMA Controller (DMA-330).

Related Information

[Arm Information Center](#)

For more information about Arm's DMA-330 controller, refer to the *CoreLink DMA Controller DMA-330 Revision: r1p2* Technical Reference Manual on the Arm Infocenter website.

Features of the DMA Controller

The HPS provides one DMAC to handle the data transfer between memory-mapped peripherals and memories, off-loading this work from the microprocessor unit (MPU) subsystem.

The DMAC supports multiple transfer types:

- Memory-to-memory
- Memory-to-peripheral
- Peripheral-to-memory

The DMAC supports up to:

- Eight logical channels for different levels of service requirements
- 31 peripheral handshake interfaces for peripheral hardware flow control

The DMAC provides:

- An instruction processing block that enables it to process program code that controls a DMA transfer
- An Arm Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) master interface unit to fetch the program code from system memory into its instruction cache

Note: The AXI master interface also performs DMA data transfer. The DMA instruction execution engine executes the program code from its instruction cache and schedules read or write AXI instructions through the respective instruction queues.

- A multi-FIFO (MFIFO) data buffer that stores data that it reads, or writes, during a DMA transfer
- 11 interrupt outputs to enable efficient communication of events to the MPU subsystem

Note: The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory transfers to occur, without intervention from the processor.

ALTERA
now part of Intel

The DMAC supports the following interface protocols:

- Synopsys protocol
 - Serial peripheral interface (SPI)
 - Universal asynchronous receiver/transmitter (UART)
 - Inter-integrated circuit (I²C)
 - FPGA
- Arm protocol
 - Quad SPI flash controller
 - System trace macrocell (STM)
- Bosch CAN
 - Two CAN controllers

Dual slave interfaces enable the operation of the DMA controller to be partitioned into the secure state and non-secure state. The network interconnect must be configured to ensure that only secure transactions can access the secure interface. The slave interfaces can access status registers and also directly execute instructions in the DMA controller.

The DMAC has the following features:

- A small instruction set that provides a flexible method of specifying the DMA operations. This architecture provides greater flexibility than the fixed capabilities of a Linked-List Item (LLI) based DMA controller.
- Supports multiple transfer types:
 - Memory-to-memory
 - Memory-to-peripheral
 - Peripheral-to-memory
 - Scatter-gather
- Supports up to eight DMA channels.
- Supports up to eight outstanding AXI read and eight outstanding AXI write transactions.
- Enables software to schedule up to 16 outstanding read and (16) outstanding write instructions.
- Supports 11 interrupt lines into the MPU subsystem⁽⁵⁵⁾:
 - One for DMA thread abort
 - Eight for events
 - Two for MFIFO buffer ECC
- Single and double bit ECC support
- Supports 31 peripheral request interfaces:
 - Four for FPGA
 - Four shared for FPGA or Controller area network (CAN)
 - Four for I²C
 - Four for I²C (EMAC)
 - Eight for SPI
 - Two for quad SPI
 - One for System Trace Macrocell (STM)
 - Four for UART

⁽⁵⁵⁾ For a description of these interrupts, refer to the "Using Events and Interrupts" chapter.

DMA Controller Block Diagram and System Integration

The following figure shows a block diagram of the DMAC and how it integrates into the rest of the HPS system.

Figure 17-1: DMA Controller Connectivity

The `l4_main_clk` clock drives the DMA controller, controller logic, and all the interfaces. The DMA controller accesses the level 3 (L3) main switch with its 64-bit AXI master interface.

The DMA controller provides the following slave interfaces:

- Non-secure slave interface
- Secure slave interface

You can use these slave interfaces to access the registers that control the functionality of the DMA controller. Since the DMA controller supports some peripherals that do not comply with the Arm DMA peripheral interface protocol, some adapters are developed to allow these peripherals to work with the DMAC.

Functional Description of the DMA Controller

This section describes the major interfaces and components of the DMAC and its operation.

The DMAC contains an instruction processing block that processes program code to control a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI master interface. The DMAC stores instructions temporarily in an internal cache.

The DMAC has eight DMA channels. Each channel supports a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads.

The DMAC executes one instruction per clock cycle. To ensure that it regularly executes each active thread, the DMAC alternates by processing the DMA manager thread and then a DMA channel thread. It performs a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate program counter (PC) register for each DMA channel.

The DMAC includes a 16-line instruction cache to improve the instruction fetch performance. Each instruction cache line contains eight, four-byte words for a total cache line size of 32 bytes. The DMAC instruction cache size is therefore 16 lines times 32 bytes per line which equals 512 bytes. When a thread requests an instruction from an address, the cache performs a lookup. If a cache hit occurs, then the cache immediately provides the instruction. Otherwise, the thread is stalled while the DMAC performs a cache line fill through the AXI master interface. If an instruction spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the instruction.

Note: When a cache line fill is in progress, the DMAC enables other threads to access the cache. But if another cache miss occurs, the pipeline stalls until the first line fill is complete.

When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI. The DMAC also contains an MFIFO data buffer in which it stores data that it reads or writes during a DMA transfer.

The DMAC provides multiple interrupt outputs to enable efficient communication of events to the system CPUs. The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory DMA transfers to occur without intervention from the microprocessor.

Dual slave interfaces enable the operation of the DMAC to be partitioned into the secure state and non-secure states. You can access status registers and also directly execute instructions in the DMAC with the slave interfaces.

Peripheral Request Interface

The following figure shows that the peripheral request interface consists of a peripheral request bus and a DMAC acknowledge bus that use the prefixes:

- `dr`—The peripheral request bus
- `da`—The DMAC acknowledge bus

Figure 17-2: Request and Acknowledge Buses on the Peripheral Request Interface

Both buses use the valid and ready handshake that the AXI protocol describes.

The peripheral uses `drtype[1:0]` to either:

- Request a single transfer
- Request a burst transfer
- Acknowledge a flush request

The peripheral uses `drlast` to notify the DMAC that the request on `drtype[1:0]` is the last request of the DMA transfer sequence. `drlast` is transferred at the same time as `drtype[1:0]`.

The DMAC can indicate the following using `datatype[1:0]`:

- When it completes the requested single transfer
- When it completes the requested burst transfer
- When it issues a flush request

Note: If you configure the DMAC to provide more than one peripheral request interface, each interface is assigned a unique identifier, `_<x>` where `<x>` represents the number of the interface.

For the Synopsys protocol, the following signals are used in the handshaking protocol:

- `dma_tx_req_n`
- `dma_rx_req_n`
- `dma_tx_ack_n`
- `dma_rx_ack_n`
- `dma_tx_single_n`
- `dma_rx_single_n`

Peripheral Request Interface Mapping

You can assign a peripheral request interface to any of the DMA channels. When a DMA channel thread executes `DMAWFP`, the value programmed in the peripheral [4:0] field specifies the peripheral associated with that DMA channel.

The DMAC supports 32 peripheral request handshakes. Each request handshake can receive up to four outstanding requests, and is assigned a specific peripheral device ID. The following table lists the peripheral device ID assignments.

Table 17-1: Peripheral Request Interface Mapping

Peripheral	Request Interface ID	Protocol
FPGA 0	0	Synopsys
FPGA 1	1	Synopsys
FPGA 2	2	Synopsys
FPGA 3	3	Synopsys
FPGA 4 /CAN 0 interface 1	4	Synopsys (FPGA) / Bosch (CAN)
FPGA 5 /CAN 0 interface 2	5	Synopsys (FPGA) / Bosch (CAN)
FPGA 6 /CAN 1 interface 1	6	Synopsys (FPGA) / Bosch (CAN)
FPGA 7 /CAN 1 interface 2	7	Synopsys (FPGA) / Bosch (CAN)
I ² C 0 Tx	8	Synopsys
I ² C 0 Rx	9	Synopsys
I ² C 1 Tx	10	Synopsys
I ² C 1 Rx	11	Synopsys
I ² C 2 Tx (EMAC)	12	Synopsys
I ² C 2 Rx (EMAC)	13	Synopsys
I ² C 3 Tx (EMAC)	14	Synopsys
I ² C 3 Rx (EMAC)	15	Synopsys
SPI Master 0 Tx	16	Synopsys
SPI Master 0 Rx	17	Synopsys
SPI Slave 0 Tx	18	Synopsys
SPI Slave 0 Rx	19	Synopsys
SPI Master 1 Tx	20	Synopsys
SPI Master 1 Rx	21	Synopsys
SPI Slave 1 Tx	22	Synopsys

Peripheral	Request Interface ID	Protocol
SPI Slave 1 Rx	23	Synopsys
Quad SPI Flash Tx	24	Arm
Quad SPI Flash Rx	25	Arm
STM	26	Arm
Reserved	27	N/A
UART 0 Tx	28	Synopsys
UART 0 Rx	29	Synopsys
UART 1 Tx	30	Synopsys
UART 1 Rx	31	Synopsys

Note: Request interface numbers 4 through 7 are multiplexed between the CAN controllers and soft logic implemented in the FPGA fabric. The switching between the CAN controller and FPGA interfaces is controlled by the system manager.

DMA Controller Address Map and Register Definitions

The following DMAC register map spans a 4 KB region, consists of the following sections.

Figure 17-3: DMAC Summary Register Map

- **Control registers**— allow you to control the DMAC.
- **DMA channel thread status registers**—provide the status of the DMA channel threads.
- **AXI and loop counter status registers**—provide the AXI transfer status and the loop counter status for each DMA channel thread.
- **Debug registers**—enable the following functionality:
 - Allow you to send instructions to a thread when debugging the program code.
 - Allow system firmware to send instructions to the DMA manager thread.
- **Configuration registers**—enable system firmware to identify the configuration of the DMAC and control the behavior of the watchdog.
- **Component ID registers**— enable system firmware to identify peripherals. Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in an unpredictable behavior.

Address Map and Register Definitions

The address map and register definitions for the DMA Controller consist of the following regions:

- Nonsecure DMA Module Address Space
- Secure DMA Module Address Space

Secure DMA Module Address Map on page 17-9

This address space is allocated for secure DMA accesses. For detailed information about the use of this address space, [click here](#) to access the Arm documentation for the DMA-330.

Send Feedback

The hard processor system (HPS) provides two Ethernet media access controller (EMAC) peripherals. Each EMAC can be used to transmit and receive data at 10/100/1000 Mbps over Ethernet connections in compliance with the IEEE 802.3 specification. The EMACs are instances of the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC (DWC_gmac).

The EMAC has an extensive memory-mapped control and status register (CSR) set, which can be accessed by the Arm Cortex-A9 MPCore.

For an understanding of this chapter, you should be familiar with the basics of IEEE 802.3 media access control (MAC).⁽⁵⁶⁾

Features of the Ethernet MAC

MAC

- IEEE 802.3-2008 compliant
- Data rates of 10/100/1000 Mbps
- Full duplex and half duplex modes
 - IEEE 802.3x flow control automatic transmission of zero-quanta pause frame on flow control input deassertion
 - Optional forwarding of received pause control frames to the user
 - Packet bursting and frame extension in 1000 Mbps half-duplex
 - IEEE 802.3x flow control in full-duplex
 - Back-pressure support for half-duplex
- 4 KB TX FIFO RAM and 4 KB RX FIFO RAM with ECC support
- IEEE 1588-2002 and IEEE 1588-2008 precision networked clock synchronization
- IEEE 802.3-az, version D2.0 for Energy Efficient Ethernet (EEE)
- IEEE 802.1Q Virtual Local Area Network (VLAN) tag detection for reception frames
- Preamble and start-of-frame data (SFD) insertion in transmit and deletion in receive paths
- Automatic cyclic redundancy check (CRC) and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length supporting standard and jumbo Ethernet frames (with size up to 3800 bytes)
- Programmable inter-frame gap (IFG), from 40- to 96-bit times in steps of eight bits
- Preamble lengths of one, three, five and seven bytes supported
- Supports internal loopback asynchronous FIFO on the GMII/MII for debugging
- Supports a variety of flexible address filtering modes
 - Up to 31 additional 48-bit perfect destination address (DA) filters with masks for each byte
 - Up to 31 48-bit source address (SA) comparison check with masks for each byte
 - 256-bit hash filter (optional) for multicast and unicast DAs
 - Option to pass all multicast addressed frames
 - Promiscuous mode support to pass all frames without any filtering for network monitoring
 - Passes all incoming packets (as per filter) with a status report

DMA

- 32-bit interface
- Programmable burst size for optimal bus utilization
- Single-channel mode transmit and receive engines
- Byte-aligned addressing mode for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptors can each transfer up to 8 KB of data
- Independent DMA arbitration for transmit and receive with fixed priority or round robin

Management Interface

- 32-bit host interface to CSR set
- Comprehensive status reporting for normal operation and transfers with errors
- Configurable interrupt options for different operational conditions
- Per-frame transmit/receive complete interrupt control
- Separate status returned for transmission and reception packets

Acceleration

- Transmit and receive checksum offload for transmission control protocol (TCP), user datagram protocol (UDP), or Internet control message protocol (ICMP) over Internet protocol (IP)

PHY Interface

Different external PHY interfaces are provided depending on whether the Ethernet Controller signals are routed through the HPS I/O pins or the FPGA I/O pins.

The PHY interfaces supported using the HPS I/O pins are:

- Reduced Gigabit Media Independent Interface (RGMII)

The PHY interfaces supported using the FPGA I/O pins are:

- Media Independent Interface (MII)
- Gigabit Media Independent Interface (GMII)
- Reduced Media Independent Interface (RMII) with additional required adaptor logic

Note: Additional adaptor logic for RMII not provided.

- Reduced Gigabit Media Independent Interface (RGMII) with additional required adaptor logic
- Serial Gigabit Media Independent Interface (SGMII) supported through transceiver I/O

The Ethernet Controller has two choices for the management control interface used for configuration and status monitoring of the PHY:

- Management Data Input/Output (MDIO)
- I²C PHY management through a separate I²C module within the HPS

EMAC Block Diagram and System Integration

Figure 18-1: EMAC System Integration

The EMACs are integrated into the HPS portion of the system on a chip (SoC) device. They communicate with the I/O pins.

EMAC Overview

Each EMAC is an internal bus master that sends Ethernet packets to and from the System Interconnect. The EMAC uses a descriptor ring protocol, where the descriptor contains an address to a buffer to fetch or store the packet data.

Each EMAC has an MDIO Management port to send commands to the external PHY. Alternatively, you can use an I²C module in the HPS for the management interface.

Each EMAC has an IEEE 1588 Timestamp interface with 20 ns resolution. The Arm Cortex-A9 microprocessor unit (MPU) subsystem can use it to maintain synchronization between the time counters that are internal to the three MACs. The clock reference for the timestamp can be provided by the Clock

Manager (`emac_ptp_clk`) or the FPGA fabric (`f2s_emac_ptp_ref_clk`). The clock reference is selected by the `ptp_clk_sel` bit in the `emac_global` register in the system manager.

EMAC Signal Description

The EMAC provides a variety of PHY interfaces and control options through the HPS and the FPGA I/Os.

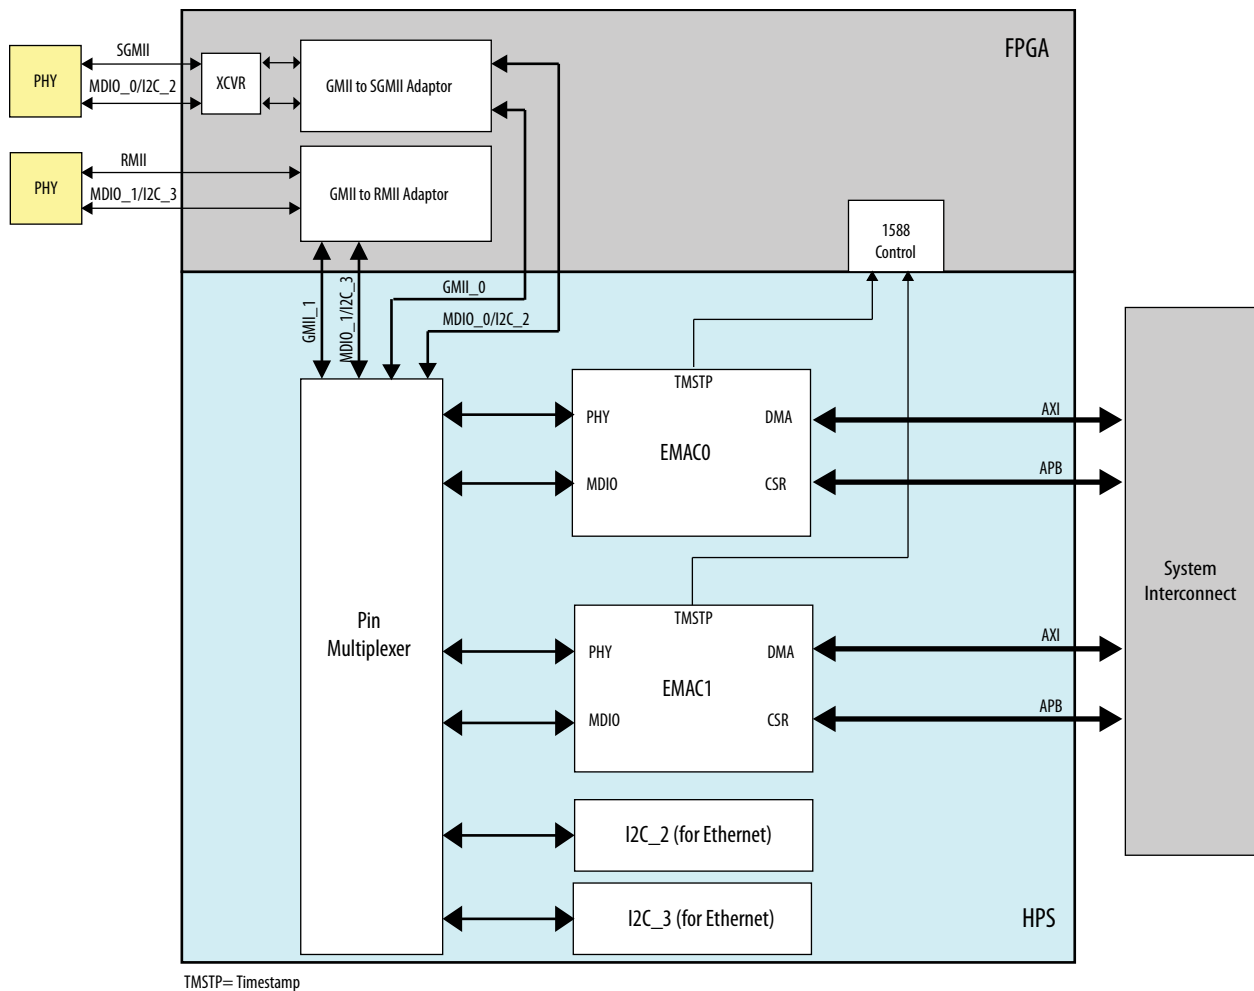

For designs in which the HPS is pin-limited, the EMAC signals can be routed through the FPGA as any one of the following interfaces by using soft adaptor logic in the FPGA:

- RMII/RGMII
- MII/GMII
- SGMII

The figure below depicts a design which routes the EMAC0 and EMAC1 signals through the FPGA to provide an RMII and SGMII interface.

Refer to the "EMAC FPGA Interface Initialization" section to find out more information about configuring EMAC interfaces through FPGA.

Figure 18-2: EMAC to FPGA Routing Example

Note: The Micrel KSZ9021RN Ethernet PHY has been verified to work properly with the HPS EMAC and is recommended for use in board design.

HPS EMAC I/O Signals

The following table lists the EMAC signals that are routed to the HPS pins. These signals provide the RGMII interface.

Table 18-1: HPS EMAC I/O Signals

EMAC Port		In/Out	Width	Description
phy_txclk_o	Transmit Clock	Out	1	This signal provides the transmit clock for RGMII (125/25/2.5 MHz in 1G/100M/10Mbps). All PHY transmit signals generated by the EMAC are synchronous to this clock.
phy_txd_o	PHY Transmit Data	Out	8	This group of eight transmit data signals is driven by the MAC. Bits [3:0] provide the RGMII transmit data. Unused bits in the RGMII interface configuration are tied low. In RGMII mode, the data bus carries transmit data at double rate and are sampled on both the rising and falling edges of the transmit clock. The validity of the data is qualified with phy_txen_o.
phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC component, and in RGMII mode acts as the control signal (rgmii_tctl) for the transmit data, and is driven on both edges of the transmit clock, phy_txclk_o.
phy_clk_rx_i	Receive Clock	In	1	In RGMII mode, this clock frequency is 125/25/2.5 MHz in 1 G/100 M/10 Mbps modes. It is provided by the external PHY. All PHY signals received by the EMAC are synchronous to this clock.

EMAC Port		In/Out	Width	Description
phy_rxd_i	PHY Receive Data	In	8	These eight data signals are received from the PHY and carry receive data at double rate with bits[3:0] valid on the rising edge of phy_rxclk_i, and bits[7:4] valid on the falling edge of phy_rxclk_i. The validity of the data is qualified with phy_rxdv_i.
phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by the PHY and functions as the receive control signal used to qualify the data received on phy_rxd_i. This signal is sampled on both edges of the clock. Note that the signal phy_rxdv_i is assigned to pin RX_CTL in the device pin-out.

Note: The "n" in EMACn stands for the EMAC peripheral number.

Information on how to initialize RGMII interface

FPGA EMAC I/O Signals

Table 18-2: FPGA EMAC I/O Signals

Signal Name		In/Out	Width	Description
emac_clk_tx_i	Transmit Clock	In	1	This is the transmit clock (2.5 MHz/25 MHz) provided by the MII PHYs only. This clock comes from the FPGA Interface and is used for TX data capture. This clock is not used in GMII mode. Note: This clock must be able to perform glitch free switching between 2.5 and 25 MHz.

Signal Name		In/Out	Width	Description
emac_phy_txclk_o	Transmit Clock Output	Out	1	In GMII mode, this signal is the transmit clock output to the PHY to sample data. For MII, this clock is unused.
emac_phy_txd_o[7:0]	PHY Transmit Data	Out	8	These are a group of eight transmit data signals driven by the EMAC. All eight bits provide the GMII transmit data byte. For the lower speed MII operation, only bits[3:0] are used. The validity of the data is qualified with phy_txen_o and phy_txer_o. Synchronous to phy_txclk_o.
emac_phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC and is used in GMII mode. When driven high, this signal indicates that valid data is being transmitted on the clk_tx_o bus.
emac_phy_txer_o	PHY Transmit Error	Out	1	This signal is driven by the EMAC and when high, indicates a transmit error or carrier extension on the phy_txd bus. It is also used to signal low power states in Energy Efficient Ethernet operation.
emac_rst_clk_tx_n_o	Transmit Clock Reset output	Out	1	Transmit clock reset output to the FPGA fabric, which is the internal synchronized reset to clk_tx_int output from the EMAC. May be used by logic implemented in the FPGA fabric as desired. The reset pulse width of the rst_clk_tx_n_o signal is three transmit clock cycles.

Signal Name		In/Out	Width	Description
emac_clk_rx_i	Receive Clock	In	1	Receive clock from external PHY. For GMII, the clock frequency is 125 MHz. For MII, the receive clock is 25 MHz for 100 Mbps and 2.5 MHz for 10 Mbps.
emac_phy_rxd_i[7:0]	PHY Receive Data	In	8	This is an eight-bit receive data bus from the PHY. In GMII mode, all eight bits are sampled. The validity of the data is qualified with <code>phy_rxdv_i</code> and <code>phy_rxer_i</code> . For lower speed MII operation, only bits [3:0] are sampled. These signals are synchronous to <code>phy_clk_rx_i</code> .
emac_phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY. In GMII mode, when driven high, it indicates that the data on the <code>phy_rxd</code> bus is valid. It remains asserted continuously from the first recovered byte of the frame through the final recovered byte.
emac_phy_rxer_i	PHY Receive Error	In	1	This signal indicates an error or carrier extension (GMII) in the received frame. This signal is synchronous to <code>phy_clk_rx_i</code> .
emac_rst_clk_rx_n_o	Receive clock reset output.	Out	1	Receive clock reset output. The reset pulse width of the <code>rst_clk_rx_n_o</code> signal is three transmit clock cycles.

Signal Name		In/Out	Width	Description
emac_phy_crs_i	PHY Carrier Sense	In	1	This signal is asserted by the PHY when either the transmit or receive medium is not idle. The PHY de-asserts this signal when both transmit and receive interfaces are idle. This signal is not synchronous to any clock.
emac_phy_col_i	PHY Collision Detect	In	1	This signal, valid only when operating in half duplex, is asserted by the PHY when a collision is detected on the medium. This signal is not synchronous to any clock.

[EMAC FPGA Interface Initialization](#) on page 18-65
Information on how to initialize GMII/MII interface

PHY Management Interface

The HPS can provide support for either MDIO or I²C PHY management interfaces.

MDIO Interface

The MDIO interface signals are synchronous to 14_mp_clk in all supported modes.

Note: The MDIO interface signals can be routed to both the FPGA and HPS I/O.

Table 18-3: PHY MDIO Management Interface

Signal	In/Out	Width	Description
emac_gmii_mdi_i	In	1	Management Data In. The PHY generates this signal to transfer register data during a read operation. This signal is driven synchronously with the gmii_mdco clock.
emac_gmii_mdo_o	Out	1	Management Data Out. The EMAC uses this signal to transfer control and data information to the PHY.

Signal	In/Out	Width	Description
emac_gmii_mdo_o_e	Out	1	Management Data Output Enable. This enable signal drives the gmii_mdo_o signal from an external three-state I/O buffer. This signal is asserted whenever valid data is driven on the gmii_mdo_o signal. The active state of this signal is high.
emac_gmii_mdc_o	Out	1	Management Data Clock. The EMAC provides timing reference for the gmii_mdi_i and gmii_mdo_o signals on MII through this aperiodic clock. The maximum frequency of this clock is 2.5 MHz. This clock is generated from the application clock through a clock divider.

I²C External PHY Management Interface

Some PHY devices use the I²C instead of MDIO for their control interface. Small form factor pluggable (SFP) optical or pluggable modules are often among those with this interface.

The HPS or FPGA can use two of the four general purpose I²C peripherals for controlling the PHY devices:

- I2C2 at base address 0xFFC06000
- I2C3 at base address 0xFFC07000

EMAC Internal Interfaces

DMA Master Interface

The DMA interface acts as a bus master on the system interconnect. Two types of data are transferred on the interface: data descriptors and actual data packets. The interface is very efficient in transferring full duplex Ethernet packet traffic. Read and write data transfers from different DMA channels can be performed simultaneously on this port, except for transmit descriptor reads and write-backs, which cannot happen simultaneously.

DMA transfers are split into a software configurable number of burst transactions on the interface. The AXI_Bus_Mode register in the dmagrp group is used to configure bursting behavior.

The interface assigns a unique ID for each DMA channel and also for each read DMA or write DMA request in a channel. Data transfers with distinct IDs can be reordered and interleaved.

The DMA interface can be configured to perform cacheable accesses. This configuration can be done in the System Manager when the DMA interface is inactive.

Write data transfers are generally performed as posted writes with OK responses returned as soon as the system interconnect has accepted the last beat of a data burst. Descriptors (status or timestamp), however, are always transferred as non-posted writes in order to prevent race conditions with the transfer complete interrupt logic.

The slave may issue an error response. When that happens, the EMAC disables the DMA channel that generated the original request and asserts an interrupt signal. The host must reset the EMAC with a hard or soft reset to restart the DMA to recover from this condition.

The EMAC supports up to 16 outstanding transactions on the interface. Buffering outstanding transactions smooths out back pressure behavior improving throughput when resource contention bottlenecks arise under high system load conditions.

Timestamp Interface

The timestamp clock reference can come from either the Clock Manager or the FPGA fabric. If the FPGA has implemented the serial capturing of the timestamp interface, then the FPGA must provide the PTP clock reference.

In addition to providing a timestamp clock reference, the FPGA can monitor the pulse-per-second output from each EMAC module and trigger a snapshot from each auxiliary time stamp timer.

The following table lists the EMAC to FPGA IEEE1588 Timestamp Interface signals to and from each EMAC module.

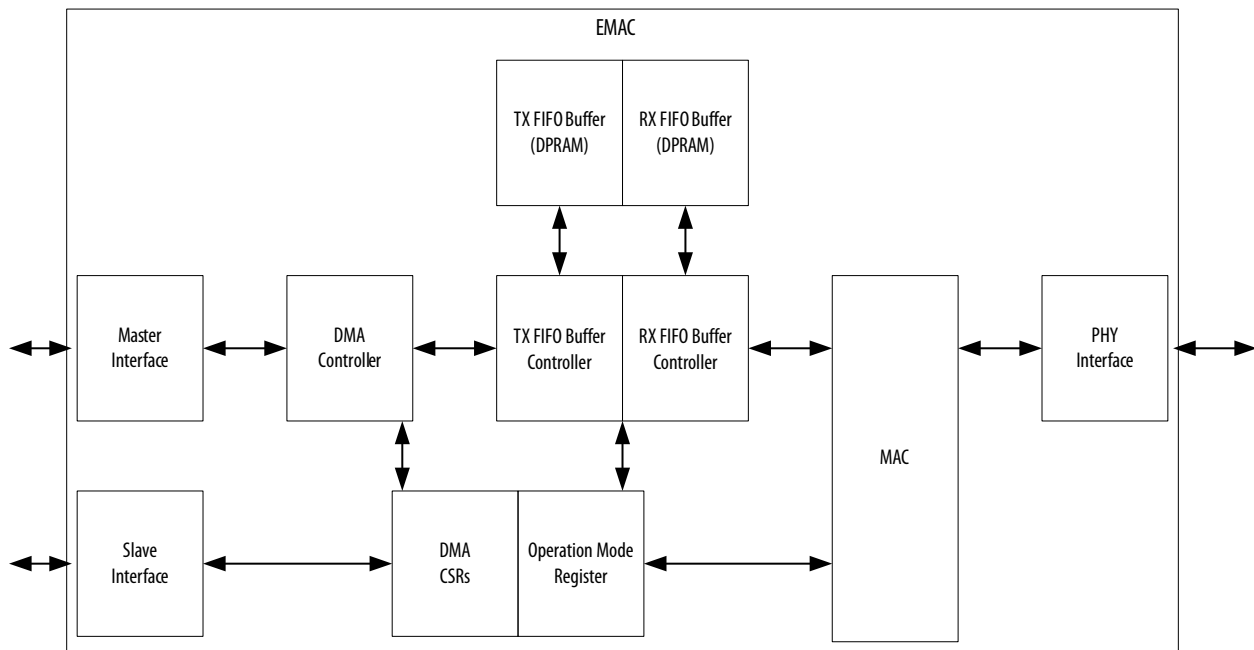

Table 18-4: EMAC to FPGA IEEE 1588 Timestamp Interface Signals

Signal Name		In/Out	Width	Description
f2h_emac_ptp_ref_clk	Timestamp PTP Clock reference from the FPGA	In	1	Used as PTP Clock reference for each EMAC when the FPGA has implemented Timestamp capture interface. Common for both EMACs.
ptp_pps_o	Pulse Per Second Output	Out	1	This signal is asserted based on the PPS mode selected in the Register 459 (PPS Control Register). Otherwise, this pulse signal is asserted every time the seconds counter is incremented. This signal is synchronous to f2h_emac_ptp_ref_clk and may only be sampled if the FPGA clock is used as timestamp reference.

Signal Name	In/Out	Width	Description
ptp_aux_ts_trig_i	In	1	<p>This signal is asserted to take an auxiliary snapshot of the time.</p> <p>The rising edge of this internal signal is used to trigger the auxiliary snapshot. The signal is synchronized internally with <code>clk_ptp_ref_i</code> which results in an additional delay of 3 cycles. This input is asynchronous input and its assertion period must be greater than 2 PTP active clocks to be sampled.</p>

Functional Description of the EMAC

Figure 18-3: EMAC High-Level Block Diagram with Interfaces

There are two host interfaces to the Ethernet MAC. The management host interface, a 32-bit slave interface, provides access to the CSR set. The data interface is a 32-bit master interface, and it controls data transfer between the direct memory access (DMA) controller channels and the rest of the HPS system through the system interconnect.

The built-in DMA controller is optimized for data transfer between the MAC controller and system memory. The DMA controller has independent transmit and receive engines and a CSR set. The transmit engine transfers data from system memory to the device port, while the receive engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal host intervention.

The EMAC also contains FIFO buffer memory to buffer and regulate the Ethernet frames between the application system memory and the EMAC module. Each EMAC module has one 4 KB TX FIFO and one 4 KB RX FIFO. On transmit, the Ethernet frames write into the transmit FIFO buffer, and eventually trigger the EMAC to perform the transfer. Received Ethernet frames are stored in the receive FIFO buffer and the FIFO buffer fill level is communicated to the DMA controller. The DMA controller then initiates the configured burst transfers. Receive and transmit transfer statuses are read by the EMAC and transferred to the DMA.

Transmit and Receive Data FIFO Buffers

Each EMAC component has associated transmit and receive data FIFO buffers to regulate the frames between the application system memory and the EMAC. Both FIFO buffer instances are 1024 x 42 bits. The FIFO buffer word consists of:

- Data: 32 bits
- Sideband:
 - Byte enables: 2 bits
 - End of frame (EOF): 1 bit
 - Error correction code (ECC): 7 bits

The data and sideband are protected by the 7-bit single error correct, double error detect (SECDED) code word.

The FIFO buffer RAMs have ECC enable, error injection and status pins. The enable and error injection pins are inputs driven by the system manager. The status pins are outputs driven to the MPU subsystem.

Note: The ECC block provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single-bit and double-bit errors for test purposes.

TX FIFO

The time at which data is sent from the TX FIFO to the EMAC is dependent on the transfer mode selected:

- Cut-through mode: Data is popped from the TX FIFO when the number of bytes in the TX FIFO crosses the configured threshold level (or when the end of the frame is written before the threshold is crossed). The threshold level is configured using the `TTC` bit of the Operation Mode Register (Register 6).

Note: After more than 96 bytes (or 548 bytes in 1000 Mbps mode) are popped to the EMAC, the TX FIFO controller frees that space and makes it available to the DMA and a retry is not possible.

- Store-and-Forward mode: Data is popped from the TX FIFO when one or more of the following conditions are true:
 - A complete frame is stored in the FIFO
 - The TX FIFO becomes almost full

The application can flush the TX FIFO of all contents by setting bit 20 (`FTF`) of Register 6 (Operation Mode Register). This bit is self-clearing and initializes the FIFO pointers to the default state. If the `FTF` bit is set during a frame transfer to the EMAC, further transfers are stopped because the FIFO is considered

empty. This cessation causes an underflow event and a runt frame to be transmitted and the corresponding status word is forwarded to the DMA.

If a collision occurs in half-duplex mode operation before an end of the frame, a retry attempt is sent before the end of the frame is transferred. When notified of the retransmission, the MAC pops the frame from the FIFO again.

Note: Only packets of 3800 bytes or less can be supported when the checksum offload feature is enabled by software.

RX FIFO

Frames received by the EMAC are pushed into the RX FIFO. The fill level of the RX FIFO is indicated to the DMA when it crosses the configured receive threshold which is programmed by the `RTC` field of Register 6 (Operation Mode Register). The time at which data is sent from the RX FIFO to the DMA is dependent on the configuration of the RX FIFO:

- Cut-through (default) mode: When 64 bytes or a full packet of data is received into the FIFO, data is popped out of the FIFO and sent to the DMA until a complete packet has been transferred. Upon completion of the end-of-frame transfer, the status word is popped and sent to the DMA.
- Store and forward mode: A frame is read out only after being written completely in the RX FIFO. This mode is configured by setting the `RSF` bit of Register 6 (Operation Mode Register).

If the RX FIFO is full before it receives the EOF data from the EMAC, an overflow is declared and the whole frame (including the status word) is dropped and the overflow counter in the DMA, (Register 8) Missed Frame and Buffer Overflow Counter Register, is incremented. This outcome is true even if the Forward Error Frame (`FEF`) bit of Register 6 (Operation Mode Register) is set. If the start address of such a frame has already been transferred, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status indicates a partial frame because of overflow. In such frames, the Frame Length field is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped.

Note: In store-and-forward mode, only received frames with length 3800 bytes or less prevent overflow errors and frames from being dropped.

DMA Controller

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory to the device port or MAC transaction layer (MTL), while the receive engine transfers data from the device port to the system memory. Descriptors are used to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as frame transmit and receive transfer completion as well as error conditions.

The DMA and the Host driver communicate through two data structures:[†]

- Control and Status registers (CSR)[†]
- Descriptor lists and data buffers[†]

Because the Cyclone V implementation of the Ethernet MAC only supports enhanced descriptors, all mentions of descriptors in the following text refer to enhanced descriptors.

Descriptor Lists and Data Buffers†

The DMA transfers data frames received by the MAC to the receive Buffer in the Host memory, and transmit data frames from the transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.†

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register), respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors (RDES1[14] and TDES0[20]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.†

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.†

Figure 18-4: Descriptor Ring Structure

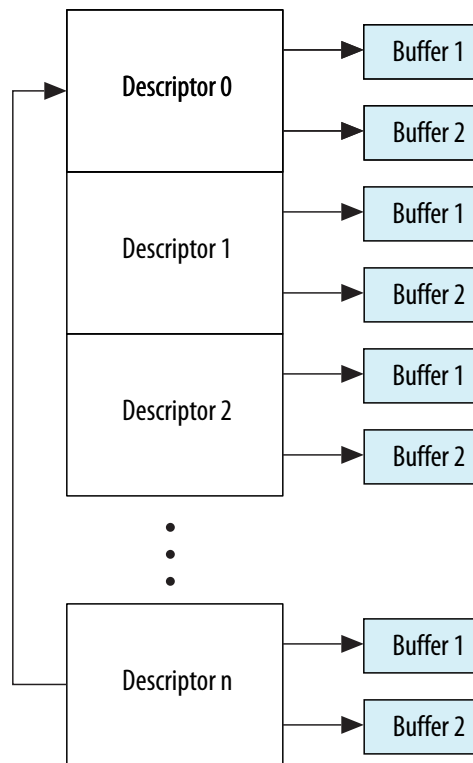

Figure 18-5: Descriptor Chain Structure

Note: You can select a descriptor structure during RTL configuration. The control bits in the descriptor structure are assigned so that the application can use an 8 KB buffer. All descriptions refer to the default descriptor structure.

Information about control and status registers

Host Bus Burst Access

The DMA attempts to execute fixed-length burst transfers on the master interface if configured to do so through the `FB` bit of Register 0 (Bus Mode Register). The maximum burst length is indicated and limited by the `PBL` field (Bits [13:8]) Register 0 (Bus Mode Register). The receive and transmit descriptors are always accessed in the maximum possible (limited by packet burst length (PBL) or $16 * 8/\text{bus width}$) burst size for the 16- bytes to be read.

The transmit DMA initiates a data transfer only when the MTL transmit FIFO has sufficient space to accommodate the configured burst or the number of bytes remaining in the frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of `INCR4`, 8, or 16 and `SINGLE` transactions. When not configured for fixed-length burst, it transfers data using `INCR` (undefined length) and `SINGLE` transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL receive FIFO buffer or when the end of frame (when it is less than the configured burst length) is detected in the receive FIFO buffer. The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of `INCR4`, 8, or 16 and `SINGLE` transactions. If the end-of-frame is reached before the fixed burst ends on the interface, then dummy transfers are performed in order to complete the fixed burst. If the `FB` bit of Register 0 (Bus Mode Register) is clear, it transfers data using `INCR` (undefined length) and `SINGLE` transactions.

When the interface is configured for address aligned words, both DMA engines ensure that the first burst transfer initiated is less than or equal to the size of the configured packet burst length. Thus, all subsequent

beats start at an address that is aligned to the configured packet burst length. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the interface does not support more than INCR16.

Host Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.[†]

Example: Buffer Read

If the transmit buffer address is 0x0000FF2, and 15 bytes must be transferred, then the DMA reads five full words from address 0x0000FF0, but when transferring data to the MTL transmit FIFO buffer, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last three bytes of the last transfer are also ignored. The DMA always ensures it transfers data in 32-bit increments to the MTL transmit FIFO buffer, unless it is the end-of-frame.

Example: Buffer Write

If the receive buffer address is 0x0000FF2 and 16 bytes of a received frame must be transferred, then the DMA writes 3 full words from address 0x0000FF0. But the first two bytes of first transfer and the last two bytes of the fourth transfer have dummy data.

Buffer Size Calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver must perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by the buffer size field of TDES1) to the MAC. If a descriptor is marked as the first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as the last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of-frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of-frame is received from the MTL. If a descriptor is not marked as the last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as the last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

Transmission

The DMA can transmit with or without an optional second frame (OSF).

Related Information

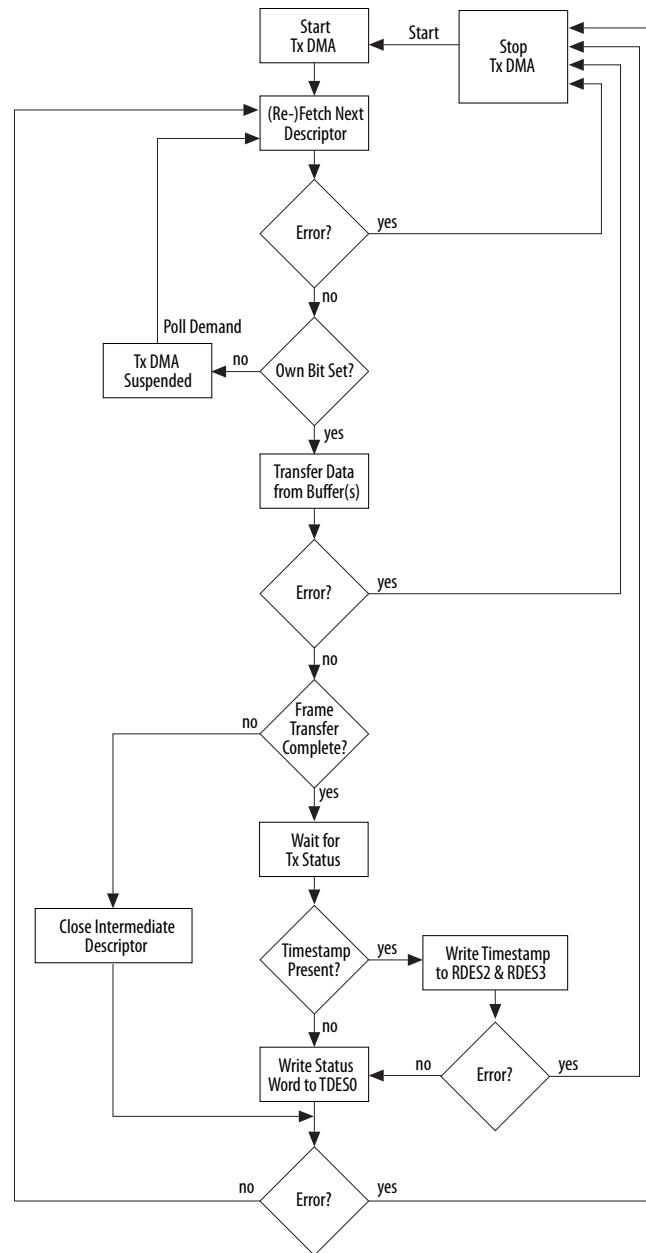

[Transmit Descriptor](#) on page 18-29

TX DMA Operation: Default (Non-OSF) Mode

The transmit DMA engine in default mode proceeds as follows: †

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data. †
2. When Bit 13 (ST) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. †
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host (TDES0[31] = 0), or if an error condition occurs, transmission is suspended and both the Bit 2 (Transmit Buffer Unavailable) and Bit 16 (Normal Interrupt Summary) of the Register 5 (Status Register) are set. The transmit Engine proceeds to [step 9](#).
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the Host memory and transfers the data to the MTL for transmission. †
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Repeat [step 3](#), [step 4](#), and [step 5](#) until the end-of-Ethernet-frame data is transferred to the MTL. †
7. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3. †
8. Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last descriptor. The DMA engine then returns to [step 3](#). †
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to [step 3](#)) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. †

Figure 18-6: TX DMA Operation in Default Mode

TX DMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first [if Bit 2 (OSF) in Register 6 (Operation Mode Register) is set]. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. †

In OSF mode, the Run state transmit DMA operates in the following sequence: †

1. The DMA operates as described in steps 1 - 6 of the **TX DMA Operation: Default (Non-OSF) Mode** on page 18-20 section.
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor. †
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to **step 7**. †
4. The DMA fetches the transmit frame from the Host memory and transfers the frame to the MTL until the End-of-frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors. †
5. The DMA waits for the previous frame's frame transmission status and timestamp. Once the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3. †
6. If enabled, the transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to **step 3** (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (**step 7**). †
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode. †
8. The DMA can exit Suspend mode and enter the Run state (go to **step 1** or **step 2** depending on pending status) only after receiving a Transmit Poll demand (Register 1 (Transmit Poll Demand Register)). †

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than two different descriptors for correct and proper operation. †

Figure 18-7: TX DMA Operation in OSF Mode

Transmit Frame Processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields and that the DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. †

Frames can be datachained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively. †

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL transmit FIFO buffer. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the transmit Process attempts to acquire the Next descriptor. The transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame. †

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) is set, the Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set, the Next descriptor is fetched, and the process repeats. †

The actual frame transmission begins after the MTL transmit FIFO buffer has reached either a program-mable transmit threshold (Bits [16:14] of Register 6 (Operation Mode Register)), or a full frame is contained in the FIFO buffer. There is also an option for Store and Forward Mode (Bit 21 of Register 6 (Operation Mode Register)). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame. †

Note: To ensure proper transmission of a frame and the next frame, you must specify a non-zero buffer size for the transmit descriptor that has the Last Descriptor (TDES1[30]) set. †

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions: †

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command. †
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. †

If the DMA goes into SUSPEND state because of the first condition, then both Bit 16 (Normal Interrupt Summary) and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) are set. If the second condition occur, both Bit 15 (Abnormal Interrupt Summary) and Bit 5 (Transmit Underflow) of Register 5 (Status Register) are set, and the information is written to Transmit Descriptor 0, causing the suspension. †

In both cases, the position in the transmit List is retained. The retained position is that of the descriptor following the Last descriptor closed by the DMA. †

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause. †

Reception

Receive functions use receive descriptors.

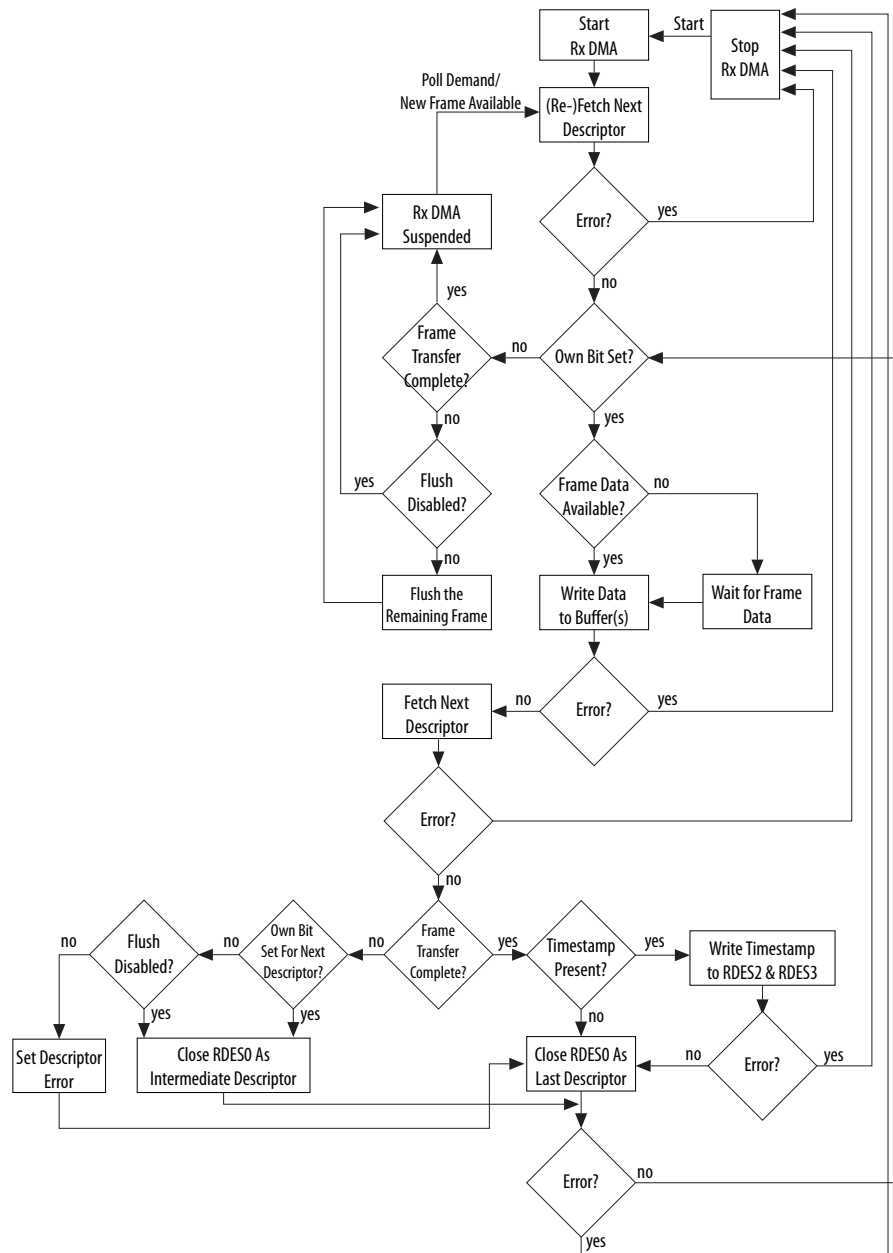

The receive DMA engine's reception sequence is proceeds as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).†
2. When Bit 1 (SR) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to [step 9](#).†
3. The DMA decodes the receive data buffer address from the acquired descriptors.†
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.†
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.†
6. If the current frame transfer is complete, the DMA proceeds to [step 7](#). If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled in Bit 24 of Register 6 (Operation

Mode Register)). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to [step 8](#). If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to [step 4](#).[†]

7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.[†]
8. The receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 0), the Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the DMA receive engine enters the Suspended state (Step 9). If the DMA owns the descriptor, the engine returns to [step 4](#) and awaits the next frame.
9. Before the receive engine enters the Suspend state, partial frames are flushed from the receive FIFO buffer. You can control flushing using Bit 24 of Register 6 (Operation Mode Register).[†]
10. The receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's receive FIFO buffer. The engine proceeds to [step 2](#) and refetches the next descriptor.[†]

Figure 18-8: Receive DMA Operation

When software has enabled timestamping through the `tsena` bit of register 448 (Timestamp Control Register) and a valid timestamp value is not available for the frame (for example, because the receive FIFO buffer was full before the timestamp could be written to it), the DMA writes all ones to RDES2 and RDES3 descriptors. Otherwise (that is, if timestamping is not enabled), the RDES2 and RDES3 descriptors remain unchanged.

Receive Descriptor Acquisition

The receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied: †

- Bit 1 (Start or Stop Receive) of Register 6 (Operation Mode Register) has been set immediately after being placed in the Run state. †
- The data buffer of the current descriptor is full before the frame ends for the current transfer. †
- The controller has completed frame reception, but the current receive descriptor is not yet closed. †
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received. †
- A Receive poll demand has been issued. †

Receive Frame Processing

The MAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to the configurable threshold bytes set for the receive FIFO buffer of MTL, or when the complete frame is written to the FIFO buffer in store-and-forward mode. †

If the frame fails the address filtering, it is dropped in the MAC block itself (unless Bit 31 (Receive All) of Register 1 (MAC Frame Filter) is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the MTL receive FIFO buffer. †

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (RDES0[9]) after the DMA Host interface becomes ready to receive a data transfer (if the DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is clear, either as the Data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES0[8]) and First Descriptor (RDES0[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets bit 6 (Receive Interrupt) of Register 5 (Status Register). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the receive process enters the Suspend state. The position in the receive list is retained. †

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the receive process re-enters the run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL RX FIFO buffer and increments the missed frame counter. If more than one frame is stored in the MTL EX FIFO buffer, the process repeats. †

The discarding or flushing of the frame at the top of the MTL EX FIFO buffer can be avoided by disabling Flushing (Bit 24 of Register 6 (Operation Mode Register)). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state. †

Interrupts

Interrupts can be generated as a result of various events. The DMA Register 5 (Status Register) contains a status bit for each of the events that can cause an interrupt. Register 7 (Interrupt Enable Register) contains an enable bit for each of the possible interrupt sources.

There are two groups of interrupts, Normal and Abnormal, as described in Register 5 (Status Register). Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts

within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the `sbd_intr_o` interrupt signal is deasserted. If the MAC is the cause for assertion of the interrupt, then any of the `GLI`, `GMI`, `TTI`, or `GLPII` bits of Register 5 (Status Register) are set to 1.

Figure 18-9: Summary Interrupt (`sbd_intr_o`) Generation⁽⁵⁷⁾

Note: Register 5 (Status Register) is the interrupt status register. The interrupt pin (`sbd_intr_o`) is asserted because of any event in this status register only if the corresponding interrupt enable bit is set in Register 7 (Interrupt Enable Register).[†]

Interrupts are not queued, and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Bit 6 (Receive Interrupt) of Register 5 (Status Register) indicates that one or more frames were transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for multiple, simultaneous events. The driver must scan Register 5 (Status Register) for the cause of the interrupt. After the driver has cleared the appropriate bit in Register 5 (Status Register), the interrupt is not generated again until a new interrupting event occurs. For example, the controller sets Bit 6 (Receive Interrupt) of Register 5 (Status Register) and the driver begins reading Register 5 (Status Register). Next, the interrupt indicated by Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) occurs. The driver clears the receive interrupt (bit 6). However, the `sbd_intr_o` signal is not deasserted, because of the active or pending Receive Buffer Unavailable interrupt.

Bits 7:0 (`riwt` field) of Register 9 (Receive Interrupt Watchdog Timer Register) provide for flexible control of the receive interrupt. When this Interrupt timer is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive Interrupt because it is not enabled in the corresponding Receive Descriptor (`RDES1[31]`). When this timer runs out as per the programmed value, the `AIS` bit is set and the interrupt is asserted if the corresponding `AIE` is enabled in Register 7 (Interrupt Enable Register). This timer is disabled before it runs out, when a frame is transferred to memory, and the receive interrupt is triggered if it is enabled.

Related Information

[Receive Descriptor](#) on page 18-36

Error Response to DMA

If the slave replies with an error response to any data transfer initiated by a DMA channel, that DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Register 5 (Status Register). The

⁽⁵⁷⁾ Signals `NIS` and `AIS` are registered.

DMA controller can resume operation only after soft resetting or hard resetting the EMAC and reinitializing the DMA.

Descriptor Overview

The DMA in the Ethernet subsystem transfers data based on a single enhanced descriptor, as explained in the DMA Controller section. The enhanced descriptor is created in the system memory. The descriptor addresses must be word-aligned.

The enhanced or alternate descriptor format can have 8 DWORDS (32 bytes) instead of 4 DWORDS as in the case of the normal descriptor format.

The features of the enhanced or alternate descriptor structure are:

- The alternative descriptor structure is implemented to support buffers of up to 8 KB (useful for Jumbo frames).[†]
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (advanced timestamp or IPC full offload configuration), and RDES1.[†]
- The transmit descriptor stores the timestamp in TDES6 and TDES7 when you select the advanced timestamp.[†]
- The receive descriptor structure is also used for storing the extended status (RDES4) and timestamp (RDES6 and RDES7) when advanced timestamp, IPC Full Checksum Offload Engine, or Layer 3 and Layer 4 filter feature is selected.[†]
- You can select one of the following options for descriptor structure:
 - If timestamping is enabled in Register 448 (Timestamp Control Register) or Checksum Offload is enabled in Register 0 (MAC Configuration Register), the software must to allocate 32 bytes (8 DWORDS) of memory for every descriptor by setting Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register).
 - If timestamping or Checksum Offload is not enabled, the extended descriptors (DES4 to DES7) are not required. Therefore, software can use descriptors with the default size of 16 bytes (4 DWORDS) by clearing Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register) to 0.

Related Information

[DMA Controller](#) on page 18-16

Transmit Descriptor

The application software must program the control bits TDES0[31:18] during the transmit descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits[7:0].

With the advance timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7 as indicated by the status Bit 17 (TTSS) of TDES0.

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Note: When the advanced timestamp feature is enabled, software should set Bit 7 of Register 0 (Bus Mode Register), so that the DMA operates with extended descriptor size. When this control bit is clear, the TDES4-TDES7 descriptor space is not valid.[†]

TDES6	Transmit Timestamp Low [31:0]																															
TDES7	Transmit Timestamp High [31:0]																															

The DMA always reads or fetches four DWORDS of the descriptor from system memory to obtain the buffer and control information. †

Figure 18-11: Transmit Descriptor Fetch (Read) Format

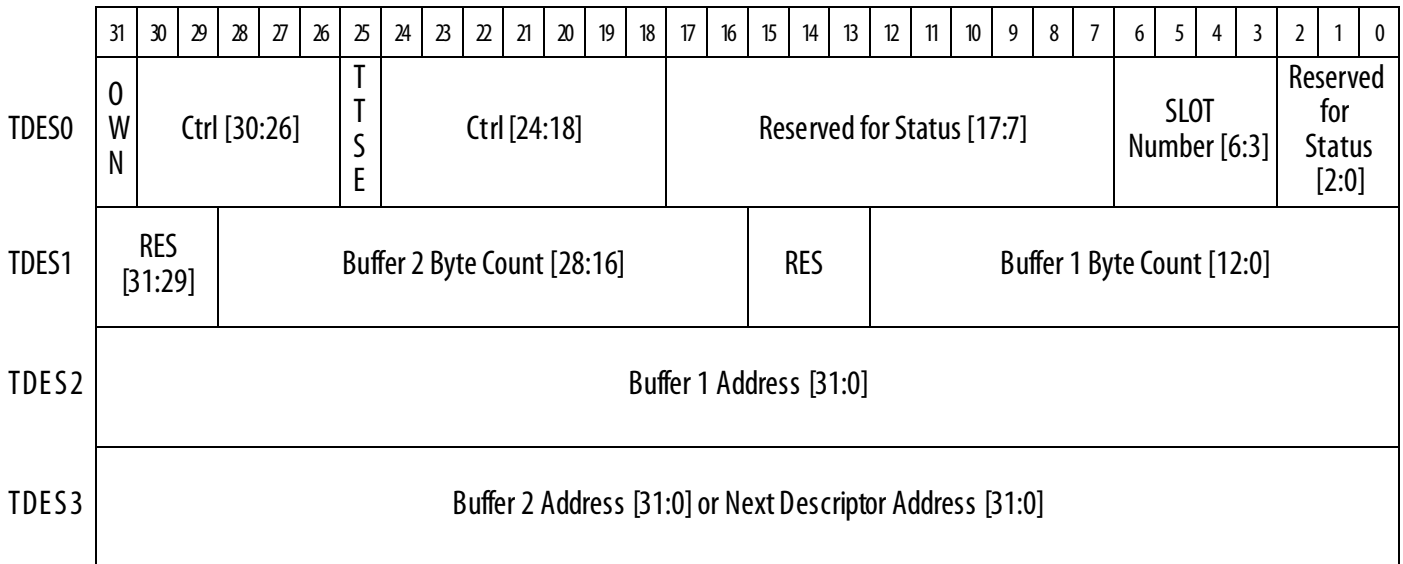

Table 18-5: Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is cleared, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set to avoid a possible race condition between fetching a descriptor and the driver setting an ownership bit. †</p>
30	<p>IC: Interrupt on Completion</p> <p>When set, this bit enables the Transmit Interrupt (Register 5[0]) to be set after the present frame has been transmitted. †</p>
29	<p>LS: Last Segment</p> <p>When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value. †</p>
28	<p>FS: First Segment</p> <p>When set, this bit indicates that the buffer contains the first segment of a frame. †</p>
27	<p>DC: Disable CRC</p> <p>When this bit is set, the MAC does not append a CRC to the end of the transmitted frame. This bit is valid only when the first segment (TDES0[28]) is set. †</p>

Bit	Description
26	<p>DP: Disable Pad</p> <p>When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is cleared, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This bit is valid only when the first segment (TDES0[28]) is set. †</p>
25	<p>TTSE: Transmit Timestamp Enable</p> <p>When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.</p>
24	Reserved
23:22	<p>CIC: Checksum Insertion Control. These bits control the checksum calculation and insertion. The following list describes the bit encoding:</p> <ul style="list-style-type: none"> ▪ 0x0: Checksum insertion disabled. ▪ 0x1: Only IP header checksum calculation and insertion are enabled. ▪ 0x2: IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware. ▪ 0x3: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware. <p>This field is valid when the First Segment control bit (TDES0[28]) is set.</p>
21	<p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †</p>
20	<p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a “don’t care” value.</p> <p>TDES0[21] takes precedence over TDES0[20]. †</p>
19:18	Reserved
17	<p>TTSS: Transmit Timestamp Status</p> <p>This field is used as a status bit to indicate that a timestamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a timestamp value captured for the transmit frame. This field is only valid when the descriptor’s Last Segment control bit (TDES0[29]) is set. †</p>

Bit	Description
16	<p>IHE: IP Header Error</p> <p>When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IPheader version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5. †</p> <p>This bit is valid only when the Tx Checksum Offload is enabled. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. †</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> ▪ TDES0[14]: Jabber Timeout ▪ TDES0[13]: Frame Flush ▪ TDES0[11]: Loss of Carrier ▪ TDES0[10]: No Carrier ▪ TDES0[9]: Late Collision ▪ TDES0[8]: Excessive Collision ▪ TDES0[2]: Excessive Deferral ▪ TDES0[1]: Underflow Error ▪ TDES0[16]: IP Header Error ▪ TDES0[12]: IP Payload Error †
14	<p>JT: Jabber Timeout</p> <p>When set, this bit indicates the MAC transmitter has experienced a jabber time-out. This bit is only set when Bit 22 (Jabber Disable) of Register 0 (MAC Configuration Register) is not set. †</p>
13	<p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA or MTL flushed the frame because of a software Flush command given by the CPU. †</p>
12	<p>IPE: IP Payload Error</p> <p>When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch. †</p>

Bit	Description
11	<p>LC: Loss of Carrier</p> <p>When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This bit is valid only for the frames transmitted without collision when the MAC operates in the half-duplex mode. †</p>
10	<p>NC: No Carrier</p> <p>When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission. †</p>
9	<p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission is aborted because of a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set.</p>
8	<p>EC: Excessive Collision</p> <p>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If Bit 9 (Disable Retry) in Register 0 (MAC Configuration Register) is set, this bit is set after the first collision, and the transmission of the frame is aborted. †</p>
7	<p>VF: VLAN Frame</p> <p>When set, this bit indicates that the transmitted frame is a VLAN-type frame. †</p>
6:3	<p>CC: Collision Count (Status field)</p> <p>These status bits indicate the number of collisions that occurred before the frame was transmitted. This count is not valid when the Excessive Collisions bit (TDES0[8]) is set. The EMAC updates this status field only in the half-duplex mode.</p>
2	<p>ED: Excessive Deferral</p> <p>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbps mode or if Jumbo frame is enabled) if Bit 4 (Deferral Check) bit in Register 0 (MAC Configuration Register) is set. †</p>
1	<p>UF: Underflow Error</p> <p>When set, this bit indicates that the MAC aborted the frame because the data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). †</p>
0	<p>DB: Deferred Bit</p> <p>When set, this bit indicates that the MAC defers before transmission because of the presence of carrier. This bit is valid only in the half-duplex mode. †</p>

Table 18-6: Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set. †
15:13	Reserved †
12:0	TBS1: Transmit Buffer 1 Size This field indicates the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). †

Table 18-7: Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. †

Table 18-8: Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES0[20]) bit is set, this address contains the pointer to the physical memory where the Next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES0[20] is set. (LSBs are ignored internally.) †

Table 18-9: Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Table 18-10: Transmit Descriptor 7 (TDES7)

Bit	Description
31:0	TTSH: Transmit Frame Timestamp High This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Receive Descriptor

The receive descriptor can have 32 bytes of descriptor data (8 DWORDs) when advanced timestamp or IPC Full Offload feature is selected. When either of these features is enabled, software should set bit 7 of Register 0 (Bus Mode Register) so that the DMA operates with extended descriptor size. When this control bit is clear, the RDES0[0] is always cleared and the RDES4-RDES7 descriptor space is not valid. †

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Figure 18-12: Receive Enhanced Descriptor Fields Format

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RDES2	Buffer 1 Address [31:0]																															
RDES3	Buffer 2 Address [31:0] or Next Descriptor Address [31:0]																															
RDES4	Extended status [31:0]																															
RDES5	Reserved																															
RDES6	Receive Timestamp Low [31:0]																															
RDES7	Receive Timestamp High [31:0]																															

Receive Descriptor Field 0 (RDES0)

Table 18-11: Receive Descriptor Field 0 (RDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA of the EMAC. When this bit is cleared, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.</p>
30	<p>AFM: Destination Address Filter Fail</p> <p>When set, this bit indicates a frame that failed in the DA Filter in the MAC. †</p>
29:16	<p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are cleared. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame.</p> <p>This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. †</p>

Bit	Description
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header or Payload Error (Receive Descriptor Field 4 (RDES4)) • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set. †</p>
14	<p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next descriptor. The frame is truncated. This bit is valid only when the Last Descriptor (RDES0[8]) bit is set. †</p>
13	<p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC. †</p>
12	<p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is clear. †</p>
11	<p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame was damaged because of buffer overflow in MTL.</p> <p>Note: This bit is set only when the DMA transfers a partial frame to the application, which happens only when the RX FIFO buffer is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in the RX FIFO buffer. †</p>

Bit	Description
10	<p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame to which this descriptor is pointing is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking the VLAN fields of the received frame based on the Register 7 (VLAN Tag Register) setting. †</p>
9	<p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame. †</p>
8	<p>LD: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame. †</p>
7	<p>Timestamp Available</p> <p>When set, bit[7] indicates that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set.</p>
6	<p>LC: Late Collision</p> <p>When set, this bit indicates that a late collision has occurred while receiving the frame in the half-duplex mode. †</p>
5	<p>FT: Frame Type</p> <p>When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600). When this bit is cleared, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.</p>
4	<p>RWT: Receive Watchdog Timeout</p> <p>When set, this bit indicates that the receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. †</p>

Bit	Description
3	<p>RE: Receive Error</p> <p>When set, this bit indicates that the <code>gmii_rxer_i</code> signal is asserted while <code>gmii_rxdv_i</code> is asserted during frame reception.</p>
2	<p>DE: Dribble Bit Error</p> <p>When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. †</p>
1	<p>CE: CRC Error</p> <p>When set, this bit indicates that a CRC error occurred on the received frame. This bit is valid only when the Last Descriptor (RDES0[8]) is set. †</p>
0	<p>Extended Status Available/RX MAC Address</p> <p>When either advanced timestamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set.</p> <p>When the Advance Timestamp Feature or IPC Full Offload is not selected, this bit indicates RX MAC Address status. When set, this bit indicates that the RX MAC Address registers value (1 to 15) matched the frame's DA field. When clear, this bit indicates that the RX MAC Address Register 0 value matched the DA field. †</p>

Receive Descriptor Field 1 (RDES1)

Table 18-12: Receive Descriptor Field 1 (RDES1)

Bit	Description
31	<p>DIC: Disable Interrupt on Completion</p> <p>When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. As a result, the RI interrupt for the frame is disabled and is not asserted to the Host.[†]</p>
30:29	Reserved [†]
28:16	<p>RBS2: Receive Buffer 2 Size</p> <p>These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer2 address pointer) in the Receive Descriptor Field 3 (RDES3) is not aligned to the bus width. If the buffer size is not an appropriate multiple of 4, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.</p>
15	<p>RER: Receive End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.[†]</p>
14	<p>RCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14].[†]</p>
13	Reserved [†]
12:0	<p>RBS1: Receive Buffer 1 Size</p> <p>Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, even if the value of RDES2 (buffer1 address pointer), in the Receive Descriptor Field 2 (RDES2), is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14). For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.</p>

Receive Descriptor Fields (RDES2) and (RDES3)

Receive Descriptor Field 2 (RDES2)

Table 18-13: Receive Descriptor Field 2 (RDES2)

Bit	Description
31:0	<p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the value programmed in RDES2[1:0] for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of the frame but the frame is shifted as per the actual buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. For more information about buffer address alignment, refer to the <i>Host Data Buffer Alignment</i> section.</p>

Related Information

[Host Data Buffer Alignment](#) on page 18-19

Receive Descriptor Field 3 (RDES3)

Table 18-14: Receive Descriptor Field 3 (RDES3)

Bit	Description
31:0	<p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[14]) bit in Receive Descriptor Field 1 (RDES1) is set, this address contains the pointer to the physical memory where the Next descriptor is present.</p> <p>If RDES1[14], in the Receive Descriptor Field 1 (RDES1) is set, the buffer (Next descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0. LSBs are ignored internally.) However, when RDES1[14] in the Receive Descriptor Field 1 (RDES1) is cleared, there are no limitations on the RDES3 value, except for the following condition: the DMA uses the value programmed in RDES3 [1:0] for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.</p>

IEEE 1588-2002 Timestamps

The IEEE 1588-2002 standard defines the Precision Time Protocol (PTP) that enables precise synchronization of clocks in a distributed network of devices. The PTP applies to systems communicating by local area networks supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. It is frequently used in automation systems where a collection of communicating machines such as robots must be synchronized and hence operate over a common time base.^(†)

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing and clock information.[†]

The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 18-13: Networked Time Synchronization

Master Clock Time

Slave Clock Time

The PTP uses the following process for synchronizing a slave node to a master node by exchanging the PTP messages:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 . This time must be captured, for Ethernet ports, at the PHY interface.[†]
2. The slave receives the sync message and also captures the exact time, t_2 , using its timing reference.[†]
3. The master sends a follow_up message to the slave, which contains t_1 information for later use.[†]
4. The slave sends a delay_req message to the master, noting the exact time, t_3 , at which this frame leaves the PHY interface.[†]
5. The master receives the message, capturing the exact time, t_4 , at which it enters its system.[†]
6. The master sends the t_4 information to the slave in the delay_resp message.[†]
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.[†]

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the PHY interface. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.[†]

The EMAC is intended to support IEEE 1588 operation in all modes with a resolution of 20 ns. When the two EMACs are operating in an IEEE 1588 environment, the MPU subsystem is responsible for maintaining synchronization between the time counters internal to the two MACs.

The IEEE 1588 interface to the FPGA allows the FPGA to provide a source for the `emac_ptp_ref_clk` input as well to allow it to monitor the pulse per second output from each EMAC controller.

The EMAC component provides a hardware assisted implementation of the IEEE 1588 protocol. Hardware support is for timestamp maintenance. Timestamps are updated when receiving any frame on the PHY interface, and the receive descriptor is updated with this value. Timestamps are also updated when the SFD of a frame is transmitted and the transmit descriptor is updated accordingly.[†]

Note: You may use external time-stamp clock reference to accomplish timing. Use the `set_global_assignment -name ENABLE_HPS_INTERNAL_TIMING ON` to enable timing analysis.

Reference Timing Source

To get a snapshot of the time, the EMAC takes the reference clock input and uses it to generate the reference time (64-bit) internally and capture timestamps.[†]

System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock, `clk_ptp_ref`, which can be the `emac_ptp_clk` from the HPS or the `f2s_ptp_ref_clk` from the FPGA. The `emac_ptp_clk` in the HPS is a derivative of the `osc1_clk` and is configured in the clock manager. This input reference clock is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the PHY interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, each EMAC's system time counter is written with the value in the Timestamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

With the fine correction method, a slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This protocol helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.[†]

With this method, an accumulator sums up the contents of the `Timestamp_Addend` register, as shown in the figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.[†]

Figure 18-14: Algorithm for System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division ratio (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is for example, 66 MHz, this ratio is calculated as $66 \text{ MHz} / 50 \text{ MHz} = 1.32$. Hence, the default addend value to program in the register is $2^{32} / 1.32$, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is $65 / 50$, or 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F ($2^{32} / 1.32$) must be programmed.[†]

In the above figure, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.†

Initially, the slave clock is set with `FreqCompensationValue0` in the Addend register. This value is as follows:†

$$\text{FreqCompensationValue}_0 = 2^{32} / \text{FreqDivisionRatio}^\dagger$$

If `MasterToSlaveDelay` is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise `MasterToSlaveDelay` value and re-synchronize with the master using the new value.†

The algorithm is as follows:†

- At time `MasterSyncTimen` the master sends the slave clock a sync message. The slave receives this message when its local clock is `SlaveClockTimen` and computes `MasterClockTimen` as:†

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n^\dagger$$

- The master clock count for current sync cycle, `MasterClockCountn` is given by:†

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$

(assuming that `MasterToSlaveDelay` is the same for sync cycles `n` and `n - 1`)†

- The slave clock count for current sync cycle, `SlaveClockCountn` is given by:†

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}^\dagger$$

- The difference between master and slave clock counts for current sync cycle, `ClockDiffCountn` is given by:†

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n^\dagger$$

- The frequency-scaling factor for the slave clock, `FreqScaleFactorn` is given by:†

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n^\dagger$$

- The frequency compensation value for Addend register, `FreqCompensationValuen` is given by: †

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n \times \text{FreqCompensationValue}_{n-1} - 1^\dagger$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.†

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.†

Transmit Path Functions

The MAC captures a timestamp when the start-of-frame data (SFD) is sent on the PHY interface. You can control the frames for which timestamps are captured on a per frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame. †

You can use the control bits in the transmit descriptor to indicate whether a timestamp should be capture for a frame. The MAC returns the timestamp to the software inside the corresponding transmit descriptor,

thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields. †

Receive Path Functions

The MAC captures the timestamp of all frames received on the PHY interface. The DMA returns the timestamp to the software in the corresponding receive descriptor. The timestamp is written only to the last receive descriptor. †

Timestamp Error Margin

According to the IEEE1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the PHY interface. Because the PHY interface receive and transmit clocks are not synchronous to the reference timestamp clock (`clk_ptp_ref`) a small amount of drift is introduced when a timestamp is moved between asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of two PTP clocks, meaning that the captured timestamp has a reference timing source value that is occurred within two clocks after the SFD is transmitted on the PHY interface.

Similarly, in the receive path, the error margin is three PHY interface clocks, plus up to two PTP clocks. You can ignore the error margin due to the PHY interface clock by assuming that this constant delay is present in the system (or link) before the SFD data reaches the PHY interface of the MAC. †

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the EMAC clock domain to the FPGA clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four PHY interface clock cycles and three PTP clock cycles. If the delay between two timestamp captures is less than this amount, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (20 ns resulting in 50 MHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. †

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the PHY interface clock frequency is fixed by the IEEE 1588 specification, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. †

Table 18-18: Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
100-Mbps full-duplex operation	168 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 16 clocks of preamble)	$(3 * \text{PTP}) + (4 * \text{MII}) \leq 168 * \text{MII}$, that is, $\sim 0.5 \text{ MHz } (168 - 4) * 40 \text{ ns} \div 3 = 2180 \text{ ns period}$

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
1000-Mbps half duplex operation	24 GMII clocks (4 for a jam pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	$(3 * \text{PTP}) + 4 * \text{GMII} \leq 24 * \text{GMII}$, that is, 18.75 MHz

Related Information**IEEE Standards Association**

IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.[†]

- Supports the IEEE 1588-2008 (version 2) timestamp format.[†]
- Provides an option to take a timestamp of all frames or only PTP-type frames.[†]
- Provides an option to take a timestamp of event messages only.[†]
- Provides an option to take the timestamp based on the clock type: ordinary, boundary, end-to-end, or peer-to-peer.[†]
- Provides an option to configure the EMAC to be a master or slave for ordinary and boundary clock.[†]
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.[†]
- Provides an option to measure sub-second time in digital or binary format.[†]

Related Information**IEEE Standards Association**

For more information about advanced timestamp features, refer to the *IEEE Standard 1588 - 2008 IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control System*, available on the IEEE Standards Association website.

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) messages in addition to SYNC, Delay Request, Follow-up, and Delay Response messages.[†]

Clock Types

The EMAC supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock[†]
- Boundary clock[†]
- End-to-End transparent clock[†]
- Peer-to-Peer transparent clock[†]

Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device. †

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:†

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in the `Timestamp_Control` register.†
- Maintains the data sets such as timestamp values.†

The table below shows the messages for which you can take the timestamp snapshot on the receive side for Master and slave nodes. For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the control bit (`tsver2ena`) and selecting the snapshot mode in the `Timestamp_Control` register.†

Table 18-19: Ordinary Clock: PTP Messages for Snapshot†

Master	Slave
Delay_Req	SYNC

Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action. The boundary clock is similar to the ordinary clock except for the following features:†

- The clock data sets are common to all ports of the boundary clock.†
- The local clock is common to all ports of the boundary clock. Therefore, the features of the ordinary clock are also applicable to the boundary clock.†

End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the ingress port to the egress port.†

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet inside the end-to-end transparent clock is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both ingress and egress ports only for PTP messages SYNC or Delay_req. You can take the snapshot by setting the snapshot select bits (`snaptypesel`) to b'10 in the `Timestamp_Control` register.†

The `snaptypesel` bits, along with bits 15 and 14 in the `Timestamp_Control` register, decide the set of PTP packet types for which a snapshot needs to be taken. The encoding is shown in the table below:†

Table 18-20: Timestamp Snapshot Dependency on Register Bits[†]

X is defined as a "don't care" in the table.

snaptypsel (bits[17:16])	tstmstrena (bit 15)	tsevntena (bit 14)	PTP Messages
0x0	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
0x0	0	1	SYNC
0x0	1	1	Delay_Req
0x1	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
0x1	0	1	SYNC, Pdelay_Req, Pdelay_Resp
0x1	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
0x2	X	X	SYNC, Delay_Req
0x3	X	X	Pdelay_Req, Pdelay_Resp

Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.[†]

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_resp packets is added and inserted into the correction field of the associated Pdelay_Resp_Followup packet.[†]

Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in the table below.[†]

Table 18-21: Peer-to-Peer Transparent Clock: PTP Messages for Snapshot[†]

PTP Messages
SYNC
Pdelay_Req
Pdelay_Resp

You can take the snapshot by setting the snapshot select bits (snaptypsel) to b'11 in the Timestamp Control register.[†]

Reference Timing Source

The EMAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 48-bit seconds field[†]
- Fixed pulse-per-second output[†]
- Flexible pulse-per-second output[†]
- Auxiliary snapshots (timestamps) with external events

Transmit Path Functions

The advanced timestamp feature is supported through the descriptors format.

Receive Path Functions

The MAC processes the received frames to identify valid PTP frames. You can control the snapshot of the time to be sent to the application, by using the following options:[†]

- Enable timestamp for all frames.[†]
- Enable timestamp for IEEE 1588 version 2 or version 1 timestamp.[†]
- Enable timestamp for PTP frames transmitted directly over Ethernet or UDP/IP Ethernet.[†]
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.[†]
- Enable timestamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP) only.[†]
- Enable the node to be a master or slave and select the timestamp type to control the type of messages for which timestamps are taken.[†]

The DMA returns the timestamp to the software inside the corresponding transmit or receive descriptor.

Auxiliary Snapshot

The auxiliary snapshot feature allows you to store a snapshot (timestamp) of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i` from the FPGA. One auxiliary snapshot input is available. The depth of the auxiliary snapshot FIFO buffer is 16.

The timestamps taken for any input are stored in a common FIFO buffer. The host can read Register 458 (Timestamp Status Register) to know which input's timestamp is available for reading at the top of this FIFO buffer.

Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from Register 457 (System Time - Higher Word Seconds Register) when it is present. When a snapshot is stored, the MAC indicates this to the host with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (`ATSSTM`) is set in Register 458 (Timestamp Status Register). This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full. When a host reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting Bit 19 (`ATSFC`) in Register 448 (Timestamp Control Register). When multiple snapshots are present in the FIFO, the count is indicated in Bits [27:25], `ATSNS`, of Register 458 (Timestamp Status Register).[†]

IEEE 802.3az Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) standardized by IEEE 802.3-az, version D2.0 is supported by the EMAC. It is supported by the MAC operating in 10/100/1000 Mbps rates. EEE is only supported when the EMAC

is configured to operate with the RGMII PHY interface operating in full-duplex mode. It cannot be used in half-duplex mode.

EEE enables the MAC to operate in Low-Power Idle (LPI) mode. Either end point of an Ethernet link can disable functionality to save power during periods of low link utilization. The MAC controls whether the system should enter or exit LPI mode and communicates this information to the PHY.[†]

Related Information

[IEEE 802.3 Ethernet Working Group](#)

For details about the *IEEE 802.3az Energy Efficient Ethernet standard*, refer to the IEEE 802.3 Ethernet Working Group website.[†]

LPI Timers

Two timers internal to the EMAC are associated with LPI mode:

- LPI Link Status (LS) Timer[†]
- LPI Time Wait (TW) Timer[†]

The LPI LS timer counts, in ms, the time expired since the link status has come up. This timer is cleared every time the link goes down and is incremented when the link is up again and the terminal count as programmed by the software is reached. The PHY interface does not assert the LPI pattern unless the terminal count is reached. This protocol ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as one second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10 bits wide, so the software can program up to 1023 ms.[†]

The LPI TW timer counts, in μ s, the time expired since the deassertion of LPI. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. The LPI TW timer is 16 bits wide, so the software can program up to 65535 μ s.[†]

The EMAC generates the LPI interrupt when the transmit or receive channel enters or exits the LPI state.[†]

Checksum Offload

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

Supported offloading types:

- Transmit IP header checksum[†]
- Transmit TCP/UDP/ICMP checksum[†]
- Receive IP header checksum[†]
- Receive full checksum[†]

Frame Filtering

The EMAC implements the following types of filtering for receive frames.

Source Address or Destination Address Filtering

The Address Filtering Module checks the destination and source address field of each incoming packet.[†]

Unicast Destination Address Filter

Up to 128 MAC addresses for unicast perfect filtering are supported. The filter compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr127 are selected with an individual enable bit. For MacAddr1–MacAddr31 addresses, you can mask each byte during comparison with the corresponding received DA byte. This enables group address filtering for the DA. The MacAddr32–MacAddr127 addresses do not have mask control and all six bytes of the MAC address are compared with the received six bytes of DA.[†]

In hash filtering mode, the filter performs imperfect filtering for unicast addresses using a 256-bit hash table. It uses the upper ten bits of the CRC of the received destination address to index the content of the hash table. A value of 0 selects Bit 0 of the selected register, and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, the unicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Multicast Destination Address Filter

The MAC can be programmed to pass all multicast frames. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported. In hash filtering mode, the filter performs imperfect filtering using a 256-bit hash table. For hash filtering, it uses the upper ten bits of the CRC of the received multicast address to index the contents of the hash table. A value of 0 selects Bit 0 of the selected register and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, then the multicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Hash or Perfect Address Filter

The filter can be configured to pass a frame when its DA matches either the hash filter or the Perfect filter. This configuration applies to both unicast and multicast frames.[†]

Broadcast Address Filter

The filter does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames, the filter drops any broadcast frame.[†]

Unicast Source Address Filter

The MAC can also perform a perfect filtering based on the source address field of the received frames. Group filtering with SA is also supported. You can filter a group of addresses by masking one or more bytes of the address.[†]

Inverse Filtering Operation (Invert the Filter Match Result at Final Output)

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. The result of the unicast or multicast destination address filter is inverted in this mode.[†]

Destination and Source Address Filtering Summary

The tables below summarize the destination and source address filtering based on the type of frames received and the configuration of bits within the Mac_Frame_Filter register.[†]

Table 18-22: Destination Address Filtering[†]

Note: The "X" in the table represents a "don't care" term.

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	Destination Address Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause frames if PCF= 0X
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause frames if PCF = 0X
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause frames if PCF = 0X
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause frames if PCF=0X
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Paus frames if PCF = 0X
	0	1	X	1	1	0	X	Fail Hash on Perfect/Group filter match and drop Pause frames if PCF = 0X

Table 18-23: Source Address Filtering[†]

Frame Type	PR	SAIF	SBF	Source Address Filter Operation
Unicast	1	X	X	Pass all frames
	0	0	0	Pass status on Perfect or Group filter match but do not drop frames that fail.
	0	1	0	Fail on Perfect or Group filter match but do not drop frame
	0	0	1	Pass on Perfect or Group filter match and drop frames that fail
	0	1	1	Fail on Perfect or Group filter match and drop frames that fail

VLAN Filtering

The EMAC supports the two kinds of VLAN filtering:

- VLAN tag-based filtering[†]
- VLAN hash filtering[†]

VLAN Tag-Based Filtering

In the VLAN tag-based frame filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. You can also enable the inverse matching for VLAN frames. In addition, you can enable matching of SVLAN tagged frames along with the default Customer Virtual Local Area Network (C-VLAN) tagged frames.[†]

VLAN Hash Filtering with a 16-Bit Hash Table

The MAC provides VLAN hash filtering with a 16-bit hash table. The MAC also supports the inverse matching of the VLAN frames. In inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.[†]

Layer 3 and Layer 4 Filters

Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering. The frames are filtered in the following ways:[†]

- Matched frames[†]
- Unmatched frames[†]
- Non-TCP or UDP IP frames[†]

Matched Frames

The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if one of the following conditions is true:[†]

- All enabled Layer 3 and Layer 4 fields match.[†]
- At least one of the enabled field matches and other fields are bypassed or disabled.[†]

Using the CSR set, you can define up to four filters, identified as filter 0 through filter 3. When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides status of the lowest filter with filter 0 being the lowest and filter 3 being the highest. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.[†]

Unmatched Frames

The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. You can configure the EMAC so that when a frame is dropped, it receives a partial frame with appropriate abort status or drops it completely.[†]

NonTCP or UDP IP Frames

By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.[†]

Layer 3 and Layer 4 Filters Register Set

The MAC implements a set of registers for Layer 3 and Layer 4 based frame filtering. In this register set, there is a control register for frame filtering and five address registers.[†]

You can configure the MAC to have up to four such independent set of registers.[†]

The registers available for programming are as follows:

- L3_L4_Control0 through L3_L4_Control3 registers: Layer and Layer 4 Control registers
- Layer4_Address0 through Layer4_Address3 registers: Layer 4 Address registers
- Layer3_Address0_Reg0 through Layer3_Address0_Reg3 registers: Layer 3 Address 0 registers
- Layer3_Address1_Reg0 through Layer3_Address1_Reg3 registers: Layer 3 Address 1 registers
- Layer3_Address2_Reg0 through Layer3_Address2_Reg3 registers: Layer 3 Address 2 registers
- Layer3_Address3_Reg0 through Layer3_Address3_Reg3 registers: Layer 3 Address 3 registers

Related Information

[Ethernet MAC Address Map and Register Definitions](#) on page 18-72

Layer 3 Filtering

The EMAC supports perfect matching or inverse matching for the IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits.[†]

For IPv6 frames filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source or Destination Address should be programmed in the order defined in the IPv6 specification. The specification requires that you program the first byte of the received frame IP Source or Destination Address in the higher byte of the register. Subsequent registers should follow the same order.[†]

For IPv4 frames filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source and Destination Address should be programmed in the order defined in the IPv4 specification. The specification requires that you program the first byte of received frame IP Source and Destination Address in the higher byte of the respective register.[†]

Layer 4 Filtering

The EMAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number. †

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received frame is in the higher byte of the register. †

Clocks and Resets

Clock Structure

The Ethernet Controller received five input clocks and generates one output clock.

The EMAC controller provides the clock division and muxing necessary to generate the proper clocks for each of the PHY modes and data rates. The clock domains to the Ethernet controller are as follows

- l4_mp_clk clock
- EMAC RX clock
- EMAC TX clock
- clk_ptp_ref

Figure 18-15: EMAC Clock Diagram

The diagram below summarizes the clock domains of the EMAC module:

Clock Gating for EEE

For the RGMII PHY interface, you can gate the transmit clock for Energy Efficient Ethernet (EEE) applications.

Related Information

[Programming Guidelines for Energy Efficient Ethernet](#) on page 18-69

Reset

The EMAC module accepts a single reset input, `emac_rst_n`, which is active low.

Note: In all modes, the EMAC core depends on the PHY clocks to be active for the internal EMAC clock sources to be valid.

Taking the Ethernet MAC Out of Reset

When a cold or warm reset is issued in the HPS, the Reset Manager resets the EMAC module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the Reset Manager's corresponding reset register. Before deasserting the reset signal, you must make sure the PHY

interface type and all other corresponding EMAC settings in the System Manager have been configured. For details about reset registers, refer to the "Module Reset Signals" section in the *Reset Manager* chapter. For more information about EMAC configuration in the System Manager, refer to the "System Level EMAC Configuration Registers" section.

Related Information

[Module Reset Signals](#) on page 4-5

For more information about reset registers refer to this section in the *Reset Manager* chapter.

Interrupts

Interrupts are generated as a result of specific events in the EMAC and external PHY device. The interrupt status register indicates all conditions which may trigger an interrupt and the interrupt enable register determines which interrupts can propagate.

Ethernet MAC Programming Model

The initialization and configuration of the EMAC and its interface is a multi-step process that includes system register programming in the System Manager and Clock Manager and configuration of clocks in multiple domains.

Note: When the EMAC interfaces to HPS I/O and register content is being transferred to a different clock domain after a write operation, no further writes should occur to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Thus, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).[†] If the CSR is accessed multiple times quickly, you must ensure that a minimum number of destination clock cycles have occurred between accesses.

Note: If the EMAC signals are routed through the FPGA fabric and it is assumed that the transmit clock supplied by the FPGA fabric switches within 6 transmit clock cycles, then the minimum time required between two write accesses to the same register is 10 transmit clock cycles.

System Level EMAC Configuration Registers

In addition to the registers in the Ethernet Controller, there are other system level registers in the Clock Manager, System Manager and Reset Manager that must be programmed in order to configure the EMAC and its interfaces.

The following table gives a summary of the important System Manager clock register bits that control operation of the EMAC. These register bits are static signals that must be set while the corresponding EMAC is in reset.

Table 18-24: System Manager Clock and Interface Settings

Register.Field	Description
ctrl.ptpclkssel_0 ctrl.ptpclkssel_1	1588 PTP reference clock. This bit selects the source of the 1588 PTP reference clock. <ul style="list-style-type: none"> 0x0= osc1_clk (default from Clock Manager) 0x1= fpga_ptp_ref_clk (from FPGA fabric; in this case, the FPGA must be in usermode with an active reference clock)
ctrl.physel_0 ctrl.physel_1	PHY Interface Select. These two bits set the PHY mode. <ul style="list-style-type: none"> 0x0= GMII or MII 0x1= RGMII 0x2= RMII (default) <p>Note: Selecting the 0x0 encoding routes the GMII/MII signals to the FPGA fabric only and selecting the 0x1 encoding routes the RGMII signals to the HPS only. 0x2 is not a valid encoding and depending on the interface selected, must be changed to 0x0 or 0x1 out of reset.</p>

The following table summarizes the important System Manager configuration register bits. All of the fields, except the AXI cache settings, are assumed to be static and must be set before the EMAC is brought out of reset. If the FPGA interface is used, the FPGA must be in user mode and enabled with the appropriate clock signals active before the EMAC can be brought out of reset.

Table 18-25: System Manager Static Control Settings

Register.Field	Description
module.emac_0 module.emac_1	FPGA interface to EMAC disable. This field is used to disable signals from the FPGA to the EMAC modules that could potentially interfere with their normal operation <ul style="list-style-type: none"> 0x0= Disable (default) 0x1=Enable
l3master.awcache_1 l3master.awcache_0 l3master.arcache_1 l3master.arcache_0	EMAC AXI Master AxCACHE settings. It is recommended that these bits are set while the EMAC is idle or in reset.

Various registers within the Clock Manager must also be configured in order for the EMAC controller to perform properly.

Table 18-26: Clock Manager Settings

Register.Field	Description
emac0clk.cnt emac1clk.cnt	EMAC clock control. The cnt value in this register is used to divide the PLL VCO frequency to generate emac0clk and emac1clk.
en.emac0clk en.emac1clk	emac0clk and emac1clk output enable.

EMAC FPGA Interface Initialization

To initialize the Ethernet controller to use the FPGA GMII/MII interface, specific software steps must be followed.

In general, the FPGA interface must be active in user mode with valid PHY clocks, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate emac bit in the permodrst register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate cnt value in the emac*clk register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. If the PTP clock source is from the FPGA, ensure that the FPGA f2s_ptp_ref_clk is active.
5. The soft GMII/MII adaptor must be loaded with active clocks propagating. The FPGA must be configured to user mode and a reset to the user soft FPGA IP may be required to propagate the PHY clocks to the HPS.
6. Once all clock sources are valid, apply the following clock settings:
 - a. Program the physel_* field in the ctrl register of the System Manager (EMAC Group) to 0x0 to select the GMII/MII PHY interface.
 - b. If the PTP clock source is from the FPGA, set the ptpclkssel_* bit in the ctrl register (EMAC group) of the System Manager to be 0x1.
 - c. Enable the Ethernet Controller FPGA interface by setting the emac_* bit in the module register of the System Manager (FPGA Interface group).
7. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCACHE signal values which are programmed in l3 register in the EMAC group of the System Manager.
8. Execute a register read back to confirm the clock and static configuration settings are valid.
9. After confirming the settings are valid, software can clear the emac bit in the permodrst register of the Reset Manager to bring the EMAC out of reset.

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

Note: These same steps can be applied to convert the HPS GMII to an RGMII, RMII or SGMII interface through the FPGA, except that in step 5 during FPGA configuration, you would load the appropriate soft adaptor for the interface and apply reset to it as well. The PHY interface select encoding would remain as 0x0. For the SGMII interface additional external transceiver logic would

be required. Routing the Ethernet signals through the FPGA is useful for designs that are pin-limited in the HPS.

EMAC HPS Interface Initialization

To initialize the Ethernet controller to use the HPS interface, specific software steps must be followed including selecting the correct PHY interface through the System Manager.

In general, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac` bit in the `permodrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate `cnt` value in the `emac*clk` register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. When all the clocks are valid, program the following clock settings:
 - a. Set the `physe1_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x1 to select the RGMII PHY interface.
 - b. Disable the Ethernet Controller FPGA interfaces by clearing the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).
5. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values, which are programmed in `l3_register` in the EMAC group of the System Manager.
6. Execute a register read back to confirm the clock and static configuration settings are valid.
7. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

DMA Initialization

This section provides the instructions for initializing the DMA registers in the proper sequence. This initialization sequence can be done after the EMAC interface initialization has been completed. Perform the following steps to initialize the DMA:

1. Provide a software reset to reset all of the EMAC internal registers and logic. (DMA Register 0 (Bus Mode Register) – bit 0).[†]
2. Wait for the completion of the reset process (poll bit 0 of the DMA Register 0 (Bus Mode Register), which is only cleared after the reset operation is completed).[†]
3. Poll the bits of Register 11 (AXI Status) to confirm that all previously initiated (before software reset) or ongoing transactions are complete.

Note: If the application cannot poll the register after soft reset (because of performance reasons), then it is recommended that you continue with the next steps and check this register again (as mentioned in step 12 on page 1-67) before triggering the DMA operations.[†]

4. Program the following fields to initialize the Bus Mode Register by setting values in DMA Register 0 (Bus Mode Register):[†]

- Mixed Burst and AAL
 - Fixed burst or undefined burst[†]
 - Burst length values and burst mode values[†]
 - Descriptor Length (only valid if Ring Mode is used)[†]
5. Program the interface options in Register 10 (AXI Bus Mode Register). If fixed burst-length is enabled, then select the maximum burst-length possible on the bus (bits[7:1]).^{†(58)}
 6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (bit 31 of descriptor should be set). When OSF mode is used, at least two descriptors are required.
 7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.[†]
 8. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register) respectively).[†]
 9. Program the following fields to initialize the mode of operation in Register 6 (Operation Mode Register):
 - Receive and Transmit Store And Forward[†]
 - Receive and Transmit Threshold Control (RTC and TTC)[†]
 - Hardware Flow Control enable[†]
 - Flow Control Activation and De-activation thresholds for MTL Receive and Transmit FIFO buffers (RFA and RFD)[†]
 - Error frame and undersized good frame forwarding enable[†]
 - OSF Mode[†]
 10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit (DMA Register 5 (Status Register)).[†]
 11. Enable the interrupts by programming Register 7 (Interrupt Enable Register).[†]

Note: Perform step 12 on page 1-67 only if you did not perform step 3 on page 1-66.[†]
 12. Read Register 11 (AHB or AXI Status) to confirm that all previous transactions are complete.[†]

Note: If any previous transaction is still in progress when you read the Register 11 (AXI Status), then it is strongly recommended to check the slave components addressed by the master interface.[†]
 13. Start the receive and transmit DMA by setting SR (bit 1) and ST (bit 13) of the control register (DMA Register 6 (Operation Mode Register)).[†]

EMAC Initialization and Configuration

The following EMAC configuration operations can be performed after DMA initialization. If the EMAC initialization and configuration is done before the DMA is set up, then enable the MAC receiver (last step below) only after the DMA is active. Otherwise, the received frame could fill the RX FIFO buffer and overflow.

1. Program the `GMII Address Register` (offset 0x10) for controlling the management cycles for the external PHY. Bits[15:11] of the `GMII Address Register` are written with the Physical Layer Address

⁽⁵⁸⁾ The Cyclone V implementation supports bits [3:1].

- of the PHY before reading or writing. Bit 0 indicates if the PHY is busy and is set before reading or writing to the PHY management interface. †
2. Read the 16-bit data of the `GMIIData Register` from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits[15:11] of the `GMIIData Register`. †
 3. Provide the MAC address registers (`MAC Address0 High Register` through `MAC Address15 High Register` and `MAC Address0 Low Register` through `MAC Address15 Low Register`).
 4. Program the `Hash Table Registers 0` through 7 (offset 0x500 to 0x51C).
 5. Program the following fields to set the appropriate filters for the incoming frames in the `MAC Frame Filter Register`: †
 - Receive All †
 - Promiscuous mode †
 - Hash or Perfect Filter †
 - Unicast, multicast, broadcast, and control frames filter settings †
 6. Program the following fields for proper flow control in the `Flow Control Register`: †
 - Pause time and other pause frame control bits †
 - Receive and Transmit Flow control bits †
 - Flow Control Busy/Backpressure Activate †
 7. Program the `Interrupt Mask Register` bits, as required and if applicable for your configuration. †
 8. Program the appropriate fields in `MAC Configuration Register` to configure receive and transmit operation modes. After basic configuration is written, set bit 3 (TE) and bit 2 (RE) in this register to enable the receive and transmit state machines. †

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the EMAC DMA is actively transmitting or receiving. Software should change these parameters only when the EMAC DMA transmitter and receiver are not active.

Performing Normal Receive and Transmit Operation

For normal operation, perform the following steps: †

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive). †
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data. †
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the TX/RX poll demand registers, (`Register 1 (Transmit Poll Demand Register)` and `Register 2 (Receive Poll Demand Register)`). †
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (`Register 18 (Current Host Transmit Descriptor Register)` and `Register 19 (Current Host Receive Descriptor Register)`). †
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (`Register 20 (Current Host Transmit Buffer Address Register)` and `Register 21 (Current Host Receive Buffer Address Register)`). †

Stopping and Starting Transmission

Perform the following steps to pause the transmission for some time: †

1. Disable the transmit DMA (if applicable), by clearing bit 13 (Start or Stop Transmission Command) of Register 6 (Operation Mode Register). †
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Register 9 (Debug Register). †
3. Disable the EMAC transmitter and EMAC receiver by clearing Bit 3 (TE) and Bit 2 (RE) in Register 0 (MAC Configuration Register). †
4. Disable the receive DMA (if applicable), after making sure that the data in the RX FIFO buffer is transferred to the system memory (by reading Register 9 (Debug Register). †
5. Make sure that both the TX FIFO buffer and RX FIFO buffer are empty. †
6. To re-start the operation, first start the DMA and then enable the EMAC transmitter and receiver. †

Programming Guidelines for Energy Efficient Ethernet

Entering and Exiting the TX LPI Mode

The Energy Efficient Ethernet (EEE) feature is available in the EMAC. To use it, perform the following steps during EMAC initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values. †
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop the RX clock in LPI mode.) †
3. Program Bits[16:5], LST, and Bits[15:0], TWT, in Register 13 (LPI Timers Control Register). †
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 (PLS) of Register 12 (LPI Control and Status Register) accordingly. This update should be done whenever the link status in the PHY changes. †
5. Set Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to make the MAC enter the LPI state. The MAC enters the LPI mode after completing the transmission in progress and sets Bit 0 (TLPIEN). †

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the TX FIFO buffer, you should set Bit 19 (LPITXA) in Register 12 (LPI Control and Status Register). †

Note: To switch off the transmit clock during the LPI state, use the `sbd_tx_clk_gating_ctrl1_o` signal for gating the clock input. †

Note: To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of Register 12 (LPI Control and Status Register) to be generated. Restore the clocks before performing step 6 on page 1-69 when you want to come out of the LPI state. †

6. Clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI state. †

The MAC waits for the time programmed in Bits [15:0], TWT, before setting the TLPIEX interrupt status bit and resuming the transmission. †

Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode. †

Gating Off the CSR Clock in the RX LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY. †

1. The MAC RX enters the LPI mode and the RX LPI entry interrupt status [RLPIEN interrupt of Register 12 (LPI_Control_Status)] is set. †
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the Register 12 (LPI_Control_Status). †

After the sbd_intr_o interrupt is asserted and the MAC TX is also in the LPI mode, you can gate off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR. †

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when Register 12 is read. †

Gating Off the CSR Clock in the TX LPI Mode

The following operations are performed when Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) is set: †

1. The Transmit LPI Entry interrupt (TLPIEN bit of Register 12) is set. †
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the Register 12. †

After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR. †

To restore the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. †

After the CSR clock is resumed, clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI mode. †

Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

Generating a Single Pulse on PPS

To generate single Pulse on PPS: †

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to 0001 to instruct the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers (register 455 and 456). †

Once the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse: †

1. Program the start time for the next pulse in the Target Time registers (register 455 and 456). This time should be more than the time at which the falling edge occurs for the previous pulse. †
2. Program the width of the next PPS signal output in Register 473 (PPS0 Width Register). †
3. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to generate a single pulse on the PPS signal output after the time at which the previous pulse is de-asserted. And at the time programmed in Target Time registers. If you give this command before the previous pulse becomes

low, then the new command overwrites the previous command and the EMAC may generate only 1 extended pulse.

Generating a Pulse Train on PPS

To generate a pulse train on PPS: †

1. Program 11 or 10 (for an interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of the PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the interval value between the train of pulses on the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
5. Program Bits[3:0], PPSCMD, of Register 459 (PPS Control Register) to 0010 to instruct the MAC to generate a train of pulses on the PPS signal output with the start time programmed in the Target Time registers (register 455 and 456). By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. †
6. Program the stop value in the Target Time registers (register 455 and 456). Ensure that Bit 31 (TSTRBUSY) of Register 456 (Target Time Nanoseconds Register) is clear before programming the Target Time registers (register 455 and 456) again. †
7. Program the PPSCMD field (bit 3:0) of Register 459 (PPS Control Register) to 0100 to stop the train of pulses on the PPS signal output after the programmed stop time specified in step 6 on page 1-71 elapses. †

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in step 7 on page 1-71) by programming 0110 in the PPSCMD field before the time (programmed in step 6 on page 1-71) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in step 2 on page 1-71) elapses. †

Generating an Interrupt without Affecting the PPS

Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) enable you to program the Target Time registers (register 455 and 456) to do any one of the following: †

- Generate only interrupts. †
- Generate interrupts and the PPS start and stop time. †
- Generate only PPS start and stop time. †

To program the Target Time registers (register 455 and 456) to generate only interrupt events: †

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the target time interrupt. †
2. Program a target time value in the Target Time registers (register 455 and 456) to instruct the MAC to generate an interrupt when the target time elapses. If Bits [6:5], TRGTMODSEL, are changed (for

example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Ethernet MAC Address Map and Register Definitions

The address map and register definitions pertain to the following modules:

- EMAC Module 0
- EMAC Module 1

[Introduction to the Hard Processor System](#) on page 2-1

EMAC Module Address Map

Registers in the EMAC module.

Module Instance	Base Address
emac0	0xFF700000
emac1	0xFF702000

GMAC Register Group

Register	Offset	Width	Access	Reset Value	Description
MAC_Configuration on page 18-137	0x0	32	RW	0x0	Register 0 (MAC Configuration Register)
MAC_Frame_Filter on page 18-145	0x4	32	RW	0x0	Register 1 (MAC Frame Filter)
GMII_Address on page 18-151	0x10	32	RW	0x0	Register 4 (GMII Address Register)
GMII_Data on page 18-154	0x14	32	RW	0x0	Register 5 (GMII Data Register)
Flow_Control on page 18-155	0x18	32	RW	0x0	Register 6 (Flow Control Register)
VLAN_Tag on page 18-158	0x1C	32	RW	0x0	Register 7 (VLAN Tag Register)
Version on page 18-160	0x20	32	RO	0x1037	Register 8 (Version Register)
Debug on page 18-160	0x24	32	RO	0x0	Register 9 (Debug Register)
LPI_Control_Status on page 18-164	0x30	32	RW	0x0	Register 12 (LPI Control and Status Register)
LPI_Timers_Control on page 18-167	0x34	32	RW	0x3E80000	Register 13 (LPI Timers Control Register)

Register	Offset	Width	Access	Reset Value	Description
Interrupt_Status on page 18-168	0x38	32	RO	0x0	Register 14 (Interrupt Register)
Interrupt_Mask on page 18-171	0x3C	32	RW	0x0	Register 15 (Interrupt Mask Register)
MAC_Address0_High on page 18-172	0x40	32	RW	0x8000FFFF	Register 16 (MAC Address0 High Register)
MAC_Address0_Low on page 18-173	0x44	32	RW	0xFFFFFFFF	Register 17 (MAC Address0 Low Register)
MAC_Address1_High on page 18-174	0x48	32	RW	0xFFFF	Register 18 (MAC Address1 High Register)
MAC_Address1_Low on page 18-178	0x4C	32	RW	0xFFFFFFFF	Register 19 (MAC Address1 Low Register)
MAC_Address2_High on page 18-178	0x50	32	RW	0xFFFF	Register 20 (MAC Address2 High Register)
MAC_Address2_Low on page 18-182	0x54	32	RW	0xFFFFFFFF	Register 21 (MAC Address2 Low Register)
MAC_Address3_High on page 18-182	0x58	32	RW	0xFFFF	Register 22 (MAC Address3 High Register)
MAC_Address3_Low on page 18-186	0x5C	32	RW	0xFFFFFFFF	Register 23 (MAC Address3 Low Register)
MAC_Address4_High on page 18-186	0x60	32	RW	0xFFFF	Register 24 (MAC Address4 High Register)
MAC_Address4_Low on page 18-190	0x64	32	RW	0xFFFFFFFF	Register 25 (MAC Address4 Low Register)
MAC_Address5_High on page 18-190	0x68	32	RW	0xFFFF	Register 26 (MAC Address5 High Register)
MAC_Address5_Low on page 18-194	0x6C	32	RW	0xFFFFFFFF	Register 27 (MAC Address5 Low Register)
MAC_Address6_High on page 18-194	0x70	32	RW	0xFFFF	Register 28 (MAC Address6 High Register)
MAC_Address6_Low on page 18-198	0x74	32	RW	0xFFFFFFFF	Register 29 (MAC Address6 Low Register)
MAC_Address7_High on page 18-198	0x78	32	RW	0xFFFF	Register 30 (MAC Address7 High Register)
MAC_Address7_Low on page 18-202	0x7C	32	RW	0xFFFFFFFF	Register 31 (MAC Address7 Low Register)
MAC_Address8_High on page 18-202	0x80	32	RW	0xFFFF	Register 32 (MAC Address8 High Register)
MAC_Address8_Low on page 18-206	0x84	32	RW	0xFFFFFFFF	Register 33 (MAC Address8 Low Register)

Register	Offset	Width	Access	Reset Value	Description
MAC_Address9_High on page 18-206	0x88	32	RW	0xFFFF	Register 34 (MAC Address9 High Register)
MAC_Address9_Low on page 18-210	0x8C	32	RW	0xFFFFFFFF	Register 35 (MAC Address9 Low Register)
MAC_Address10_High on page 18-210	0x90	32	RW	0xFFFF	Register 36 (MAC Address10 High Register)
MAC_Address10_Low on page 18-214	0x94	32	RW	0xFFFFFFFF	Register 37 (MAC Address10 Low Register)
MAC_Address11_High on page 18-214	0x98	32	RW	0xFFFF	Register 38 (MAC Address11 High Register)
MAC_Address11_Low on page 18-218	0x9C	32	RW	0xFFFFFFFF	Register 39 (MAC Address11 Low Register)
MAC_Address12_High on page 18-218	0xA0	32	RW	0xFFFF	Register 40 (MAC Address12 High Register)
MAC_Address12_Low on page 18-222	0xA4	32	RW	0xFFFFFFFF	Register 41 (MAC Address12 Low Register)
MAC_Address13_High on page 18-222	0xA8	32	RW	0xFFFF	Register 42 (MAC Address13 High Register)
MAC_Address13_Low on page 18-226	0xAC	32	RW	0xFFFFFFFF	Register 43 (MAC Address13 Low Register)
MAC_Address14_High on page 18-226	0xB0	32	RW	0xFFFF	Register 44 (MAC Address14 High Register)
MAC_Address14_Low on page 18-230	0xB4	32	RW	0xFFFFFFFF	Register 45 (MAC Address14 Low Register)
MAC_Address15_High on page 18-230	0xB8	32	RW	0xFFFF	Register 46 (MAC Address15 High Register)
MAC_Address15_Low on page 18-234	0xBC	32	RW	0xFFFFFFFF	Register 47 (MAC Address15 Low Register)
SGMII_RGMII_SMII_Control_Status on page 18-234	0xD8	32	RO	0x0	Register 54 (SGMII/RGMII/SMII Status Register)
MMC_Control on page 18-236	0x100	32	RW	0x0	Register 64 (MMC Control Register)
MMC_Receive_Interrupt on page 18-238	0x104	32	RO	0x0	Register 65 (MMC Receive Interrupt Register)
MMC_Transmit_Interrupt on page 18-244	0x108	32	RO	0x0	Register 66 (MMC Transmit Interrupt Register)
MMC_Receive_Interrupt_Mask on page 18-250	0x10C	32	RW	0x0	Register 67 (MMC Receive Interrupt Mask Register)

Register	Offset	Width	Access	Reset Value	Description
MMC_Transmit_Interrupt_Mask on page 18-256	0x110	32	RW	0x0	Register 68 (MMC Transmit Interrupt Mask Register)
txoctetcount_gb on page 18-262	0x114	32	RO	0x0	Register 69 (txoctetcount_gb Register)
txframecount_gb on page 18-262	0x118	32	RO	0x0	Register 70 (txframecount_gb Register)
txbroadcastframes_g on page 18-263	0x11C	32	RO	0x0	Register 71 (txbroadcastframes_g Register)

GMAC Register Group Register Descriptions

GMAC Register Group

Offset: 0x0

[MAC_Configuration](#) on page 18-137

The MAC Configuration register establishes receive and transmit operating modes.

[MAC_Frame_Filter](#) on page 18-145

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

[GMII_Address](#) on page 18-151

The GMII Address register controls the management cycles to the external PHY through the management interface.

[GMII_Data](#) on page 18-154

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

[Flow_Control](#) on page 18-155

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the gb bit (busy bit) of the GMII_Address register set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The gb bit of the GMII_Address register remains set until the control frame is transferred onto the cable. The Host must make sure that the gb bit is cleared before writing to the register.

[VLAN_Tag](#) on page 18-158

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

[Version](#) on page 18-160

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Debug on page 18-160

The Debug register gives the status of all main blocks of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

LPI_Control_Status on page 18-164

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

LPI_Timers_Control on page 18-167

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Interrupt_Status on page 18-168

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Interrupt_Mask on page 18-171

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is `sbd_intr_o`.

MAC_Address0_High on page 18-172

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address0_Low on page 18-173

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

MAC_Address1_High on page 18-174

The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address1_Low on page 18-178

The MAC Address1 Low register holds the lower 32 bits of the 2nd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address2_High on page 18-178

The MAC Address2 High register holds the upper 16 bits of the 3rd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address2_Low on page 18-182

The MAC Address2 Low register holds the lower 32 bits of the 3rd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address3_High on page 18-182

The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address3_Low on page 18-186

The MAC Address3 Low register holds the lower 32 bits of the 4th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address4_High on page 18-186

The MAC Address4 High register holds the upper 16 bits of the 5th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address4_Low on page 18-190

The MAC Address4 Low register holds the lower 32 bits of the 5th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address5_High on page 18-190

The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address5_Low on page 18-194

The MAC Address5 Low register holds the lower 32 bits of the 6th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address6_High on page 18-194

The MAC Address6 High register holds the upper 16 bits of the 7th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address6_Low on page 18-198

The MAC Address6 Low register holds the lower 32 bits of the 7th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address7_High on page 18-198

The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address7_Low on page 18-202

The MAC Address7 Low register holds the lower 32 bits of the 8th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address8_High on page 18-202

The MAC Address8 High register holds the upper 16 bits of the 9th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address8_Low on page 18-206

The MAC Address8 Low register holds the lower 32 bits of the 9th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address9_High on page 18-206

The MAC Address9 High register holds the upper 16 bits of the 10th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address9_Low on page 18-210

The MAC Address9 Low register holds the lower 32 bits of the 10th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address10_High on page 18-210

The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address10_Low on page 18-214

The MAC Address10 Low register holds the lower 32 bits of the 11th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address11_High on page 18-214

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address11_Low on page 18-218

The MAC Address11 Low register holds the lower 32 bits of the 12th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address12_High on page 18-218

The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address12 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address12_Low on page 18-222

The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address13_High on page 18-222

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address13_Low on page 18-226

The MAC Address13 Low register holds the lower 32 bits of the 14th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address14_High on page 18-226

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_Low on page 18-230

The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address15_High on page 18-230

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address15_Low on page 18-234

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

SGMII_RGMII_SMII_Control_Status on page 18-234

The SGMII/RGMII/SMII Status register indicates the status signals received by the RGMII interface (selected at reset) from the PHY.

MMC_Control on page 18-236

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

MMC_Receive_Interrupt on page 18-238

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Transmit_Interrupt on page 18-244

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

[MMC_Receive_Interrupt_Mask](#) on page 18-250

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.

[MMC_Transmit_Interrupt_Mask](#) on page 18-256

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

[txoctetcount_gb](#) on page 18-262

Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames

[txframecount_gb](#) on page 18-262

Number of good and bad frames transmitted, exclusive of retried frames

[txbroadcastframes_g](#) on page 18-263

Number of good broadcast frames transmitted

[txmulticastframes_g](#) on page 18-264

Number of good multicast frames transmitted

[tx64octets_gb](#) on page 18-264

Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames

[tx65to127octets_gb](#) on page 18-265

Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames

[tx128to255octets_gb](#) on page 18-266

Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames

[tx256to511octets_gb](#) on page 18-266

Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames

[tx512to1023octets_gb](#) on page 18-267

Number of good and bad frames transmitted with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames

[tx1024tomaxoctets_gb](#) on page 18-268

Number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

[txunicastframes_gb](#) on page 18-269

Number of good and bad unicast frames transmitted

[txmulticastframes_gb](#) on page 18-269

Number of good and bad multicast frames transmitted

[txbroadcastframes_gb](#) on page 18-270

Number of good and bad broadcast frames transmitted

[txunderflowerror](#) on page 18-271

Number of frames aborted due to frame underflow error

txsinglecol_g on page 18-271

Number of successfully transmitted frames after a single collision in Half-duplex mode

txmulticol_g on page 18-272

Number of successfully transmitted frames after more than a single collision in Half-duplex mode

txdeferred on page 18-273

Number of successfully transmitted frames after a deferral in Halfduplex mode

txlatecol on page 18-273

Number of frames aborted due to late collision error

txexesscol on page 18-274

Number of frames aborted due to excessive (16) collision errors

txcarriererr on page 18-275

Number of frames aborted due to carrier sense error (no carrier or loss of carrier)

txoctetcnt on page 18-275

Number of bytes transmitted, exclusive of preamble, in good frames only

txframecount_g on page 18-276

Number of good frames transmitted

txexcessdef on page 18-277

Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times)

txpauseframes on page 18-277

Number of good PAUSE frames transmitted

txvlanframes_g on page 18-278

Number of good VLAN frames transmitted, exclusive of retried frames

txoversize_g on page 18-279

Number of good and bad frames received

rxframecount_gb on page 18-279

Number of good and bad frames received

rxoctetcount_gb on page 18-280

Number of bytes received, exclusive of preamble, in good and bad frames

rxoctetcount_g on page 18-281

Number of bytes received, exclusive of preamble, only in good frames

rxbroadcastframes_g on page 18-281

Number of good broadcast frames received

rxmulticastframes_g on page 18-282

Number of good multicast frames received

rxrcrcerror on page 18-282

Number of frames received with CRC error

rxalignmenterror on page 18-283

Number of frames received with alignment (dribble) error. Valid only in 10/100 mode

rxrunterror on page 18-284

Number of frames received with runt (<64 bytes and CRC error) error

rxjabbererror on page 18-284

Number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames

rxundersize_g on page 18-285

Number of frames received with length less than 64 bytes, without any errors

rxoversize_g on page 18-286

Number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames), without errors

rx64octets_gb on page 18-286

Number of good and bad frames received with length 64 bytes, exclusive of preamble

rx65to127octets_gb on page 18-287

Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble

rx128to255octets_gb on page 18-288

Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble

rx256to511octets_gb on page 18-288

Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble

rx512to1023octets_gb on page 18-289

Number of good and bad frames received with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble

rx1024tomaxoctets_gb on page 18-290

Number of good and bad frames received with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

rxunicastframes_g on page 18-291

Number of good unicast frames received

rxlengtherror on page 18-291

Number of frames received with length error (length type field not equal to frame size), for all frames with valid length field

rxoutofrangetype on page 18-292

Number of frames received with length field not equal to the valid frame size (greater than 1,500 but less than 1,536)

rxpauseframes on page 18-293

Number of good and valid PAUSE frames received

rxfifooverflow on page 18-293

Number of missed received frames due to FIFO overflow

rxvlanframes_gb on page 18-294

Number of good and bad VLAN frames received

[rxwatchdogerror](#) on page 18-295

Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2,048 bytes)

[rxrcverror](#) on page 18-295

Number of frames received with Receive error or Frame Extension error on the GMII or MII interface. While "Receive Error" is applicable to all PHY interfaces, "Frame Extension Error" can occur only for PHY interfaces that support 1G half-duplex mode.

[rxctrlframes_g](#) on page 18-296

Number of received good control frames.

[MMC_IPC_Receive_Interrupt_Mask](#) on page 18-297

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

[MMC_IPC_Receive_Interrupt](#) on page 18-303

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

[rxipv4_gd_frms](#) on page 18-309

Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload

[rxipv4_hdrerr_frms](#) on page 18-310

Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors

[rxipv4_nopay_frms](#) on page 18-311

Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine

[rxipv4_frag_frms](#) on page 18-311

Number of good IPv4 datagrams with fragmentation

[rxipv4_udsbl_frms](#) on page 18-312

Number of good IPv4 datagrams received that had a UDP payload with checksum disabled

[rxipv6_gd_frms](#) on page 18-313

Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

[rxipv6_hdrerr_frms](#) on page 18-313

Number of IPv6 datagrams received with header errors (length or version mismatch)

[rxipv6_nopay_frms](#) on page 18-314

Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers

[rxudp_gd_frms](#) on page 18-315

Number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented

[rxudp_err_frms](#) on page 18-315

Number of good IP datagrams whose UDP payload has a checksum error

[rxtcp_gd_frms](#) on page 18-316

Number of good IP datagrams with a good TCP payload

[rxtcp_err_frms](#) on page 18-317

Number of good IP datagrams whose TCP payload has a checksum error

[rxicmp_gd_frms](#) on page 18-317

Number of good IP datagrams with a good ICMP payload

[rxicmp_err_frms](#) on page 18-318

Number of good IP datagrams whose ICMP payload has a checksum error

[rxipv4_gd_octets](#) on page 18-319

Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data

[rxipv4_hdrerr_octets](#) on page 18-319

Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter

[rxipv4_nopay_octets](#) on page 18-320

Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_frag_octets](#) on page 18-321

Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_udsbl_octets](#) on page 18-321

Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes

[rxipv6_gd_octets](#) on page 18-322

Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data

[rxipv6_hdrerr_octets](#) on page 18-323

Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 headers Length field is used to update this counter

[rxipv6_nopay_octets](#) on page 18-324

Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter

[rxudp_gd_octets](#) on page 18-324

Number of bytes received in a good UDP segment. This counter does not count IP header bytes

[rxudp_err_octets](#) on page 18-325

Number of bytes received in a UDP segment that had checksum errors

[rxtcp_gd_octets](#) on page 18-326

Number of bytes received in a good TCP segment

[rxtcperroctets](#) on page 18-326

Number of bytes received in a TCP segment with checksum errors

[rxicmp_gd_octets](#) on page 18-327

Number of bytes received in a good ICMP segment

[rxicmp_err_octets](#) on page 18-328

Number of bytes received in an ICMP segment with checksum errors

[L3_L4_Control0](#) on page 18-328

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

[Layer4_Address0](#) on page 18-331

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

[Layer3_Addr0_Reg0](#) on page 18-332

For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr1_Reg0](#) on page 18-333

For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr2_Reg0](#) on page 18-334

For IPv4 frames, the Layer 3 Address 2 Register 0 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr3_Reg0](#) on page 18-335

For IPv4 frames, the Layer 3 Address 3 Register 0 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

[L3_L4_Control1](#) on page 18-336

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

[Layer4_Address1](#) on page 18-339

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

[Layer3_Addr0_Reg1](#) on page 18-340

For IPv4 frames, the Layer 3 Address 0 Register 1 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr1_Reg1](#) on page 18-340

For IPv4 frames, the Layer 3 Address 1 Register 1 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr2_Reg1](#) on page 18-341

For IPv4 frames, the Layer 3 Address 2 Register 1 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

[Layer3_Addr3_Reg1](#) on page 18-342

For IPv4 frames, the Layer 3 Address 3 Register 1 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control2 on page 18-343

This register controls the operations of the filter 2 of Layer 3 and Layer 4.

Layer4_Address2 on page 18-346

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg2 on page 18-347

For IPv4 frames, the Layer 3 Address 0 Register 2 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg2 on page 18-347

For IPv4 frames, the Layer 3 Address 1 Register 2 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg2 on page 18-348

For IPv4 frames, the Layer 3 Address 2 Register 2 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg2 on page 18-349

For IPv4 frames, the Layer 3 Address 3 Register 2 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control3 on page 18-350

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address3 on page 18-353

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg3 on page 18-354

For IPv4 frames, the Layer 3 Address 0 Register 3 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg3 on page 18-355

For IPv4 frames, the Layer 3 Address 1 Register 3 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg3 on page 18-356

For IPv4 frames, the Layer 3 Address 2 Register 3 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg3 on page 18-357

For IPv4 frames, the Layer 3 Address 3 Register 3 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

Hash_Table_Reg0 on page 18-358

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Hash_Table_Reg1 on page 18-359

This register contains the second 32 bits of the hash table.

Hash_Table_Reg2 on page 18-360

This register contains the third 32 bits of the hash table.

Hash_Table_Reg3 on page 18-360

This register contains the fourth 32 bits of the hash table.

Hash_Table_Reg4 on page 18-361

This register contains the fifth 32 bits of the hash table.

Hash_Table_Reg5 on page 18-362

This register contains the sixth 32 bits of the hash table.

Hash_Table_Reg6 on page 18-362

This register contains the seventh 32 bits of the hash table.

Hash_Table_Reg7 on page 18-363

This register contains the eighth 32 bits of the hash table.

VLAN_Hash_Table_Reg on page 18-364

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control on page 18-364

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver.

Sub_Second_Increment on page 18-370

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

System_Time_Seconds on page 18-371

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from `clk_ptp_ref_i` to `l3_sp_clk`).

System_Time_Nanoseconds on page 18-372

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set, each bit represents 1 ns and the maximum value is `0x3B9A_C9FF`, after which it rolls-over to zero.

System_Time_Seconds_Update on page 18-372

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register.

System_Time_Nanoseconds_Update on page 18-373

Update system time

Timestamp_Addend on page 18-374

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of `clk_ptp_ref_i`) and the system time is updated whenever the accumulator overflows.

Target_Time_Seconds on page 18-375

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers.

Target_Time_Nanoseconds on page 18-375

Target time

System_Time_Higher_Word_Seconds on page 18-377

System time higher word

Timestamp_Status on page 18-377

Timestamp status. All bits except Bits[27:25] get cleared when the host reads this register.

PPS_Control on page 18-379

Controls timestamp Pulse-Per-Second output

Auxiliary_Timestamp_Nanoseconds on page 18-383

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

Auxiliary_Timestamp_Seconds on page 18-383

Contains the higher 32 bits (Seconds field) of the auxiliary timestamp.

PPS0_Interval on page 18-384

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

PPS0_Width on page 18-385

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

MAC_Address16_High on page 18-386

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address16_Low on page 18-389

The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address17_High on page 18-390

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address17_Low on page 18-394

The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address18_High on page 18-394

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address18_Low on page 18-398

The MAC Address18 Low register holds the lower 32 bits of the 19th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address19_High on page 18-398

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address19_Low on page 18-402

The MAC Address19 Low register holds the lower 32 bits of the 20th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address20_High on page 18-402

The MAC Address20 High register holds the upper 16 bits of the 21th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address20_Low on page 18-406

The MAC Address20 Low register holds the lower 32 bits of the 21th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address21_High on page 18-406

The MAC Address21 High register holds the upper 16 bits of the 22th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address21_Low on page 18-410

The MAC Address21 Low register holds the lower 32 bits of the 22th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address22_High on page 18-410

The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address22_Low on page 18-414

The MAC Address22 Low register holds the lower 32 bits of the 23th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address23_High on page 18-414

The MAC Address23 High register holds the upper 16 bits of the 24th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address23 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address23_Low on page 18-418

The MAC Address23 Low register holds the lower 32 bits of the 24th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address24_High on page 18-418

The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address24_Low on page 18-422

The MAC Address24 Low register holds the lower 32 bits of the 25th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address25_High on page 18-422

The MAC Address25 High register holds the upper 16 bits of the 26th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address25 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address25_Low on page 18-426

The MAC Address25 Low register holds the lower 32 bits of the 26th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address26_High on page 18-426

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address26_Low on page 18-430

The MAC Address26 Low register holds the lower 32 bits of the 27th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address27_High on page 18-430

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address27_Low on page 18-434

The MAC Address27 Low register holds the lower 32 bits of the 28th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address28_High on page 18-434

The MAC Address28 High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address28 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address28_Low on page 18-438

The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address29_High on page 18-438

The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address29_Low on page 18-442

The MAC Address29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address30_High on page 18-442

The MAC Address30 High register holds the upper 16 bits of the 31th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_Low on page 18-446

The MAC Address30 Low register holds the lower 32 bits of the 31th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address31_High on page 18-446

The MAC Address31 High register holds the upper 16 bits of the 32th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address31_Low on page 18-450

The MAC Address31 Low register holds the lower 32 bits of the 32th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address32_High on page 18-450

The MAC Address32 High register holds the upper 16 bits of the 33th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address32 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address32_Low on page 18-454

The MAC Address32 Low register holds the lower 32 bits of the 33th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address33_High on page 18-454

The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address33_Low on page 18-458

The MAC Address33 Low register holds the lower 32 bits of the 34th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address34_High on page 18-458

The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address34_Low on page 18-462

The MAC Address34 Low register holds the lower 32 bits of the 35th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address35_High on page 18-462

The MAC Address35 High register holds the upper 16 bits of the 36th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address35 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address35_Low on page 18-466

The MAC Address35 Low register holds the lower 32 bits of the 36th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address36_High on page 18-466

The MAC Address36 High register holds the upper 16 bits of the 37th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address36 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address36_Low on page 18-470

The MAC Address36 Low register holds the lower 32 bits of the 37th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address37_High on page 18-470

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_Low on page 18-474

The MAC Address37 Low register holds the lower 32 bits of the 38th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address38_High on page 18-474

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address38_Low on page 18-478

The MAC Address38 Low register holds the lower 32 bits of the 39th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address39_High on page 18-478

The MAC Address39 High register holds the upper 16 bits of the 40th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address39 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address39_Low on page 18-482

The MAC Address39 Low register holds the lower 32 bits of the 40th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address40_High on page 18-482

The MAC Address40 High register holds the upper 16 bits of the 41th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address40_Low on page 18-486

The MAC Address40 Low register holds the lower 32 bits of the 41th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address41_High on page 18-486

The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_Low on page 18-490

The MAC Address41 Low register holds the lower 32 bits of the 42th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address42_High on page 18-490

The MAC Address42 High register holds the upper 16 bits of the 43th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address42 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address42_Low on page 18-494

The MAC Address42 Low register holds the lower 32 bits of the 43th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address43_High on page 18-494

The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_Low on page 18-498

The MAC Address43 Low register holds the lower 32 bits of the 44th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address44_High on page 18-498

The MAC Address44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address44 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address44_Low on page 18-502

The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address45_High on page 18-502

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_Low on page 18-506

The MAC Address45 Low register holds the lower 32 bits of the 46th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address46_High on page 18-506

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address46_Low on page 18-510

The MAC Address46 Low register holds the lower 32 bits of the 47th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address47_High on page 18-510

The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_Low on page 18-514

The MAC Address47 Low register holds the lower 32 bits of the 48th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address48_High on page 18-514

The MAC Address48 High register holds the upper 16 bits of the 49th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address48 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address48_Low on page 18-518

The MAC Address48 Low register holds the lower 32 bits of the 49th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address49_High on page 18-518

The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_Low on page 18-522

The MAC Address49 Low register holds the lower 32 bits of the 50th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address50_High on page 18-522

The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address50_Low on page 18-526

The MAC Address50 Low register holds the lower 32 bits of the 51th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address51_High on page 18-526

The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_Low on page 18-530

The MAC Address51 Low register holds the lower 32 bits of the 52th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address52_High on page 18-530

The MAC Address52 High register holds the upper 16 bits of the 53th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address52 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address52_Low on page 18-534

The MAC Address52 Low register holds the lower 32 bits of the 53th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address53_High on page 18-534

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_Low on page 18-538

The MAC Address53 Low register holds the lower 32 bits of the 54th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address54_High on page 18-538

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_Low on page 18-542

The MAC Address54 Low register holds the lower 32 bits of the 55th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address55_High on page 18-542

The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_Low on page 18-546

The MAC Address55 Low register holds the lower 32 bits of the 56th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address56_High on page 18-546

The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address56_Low on page 18-550

The MAC Address56 Low register holds the lower 32 bits of the 57th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address57_High on page 18-550

The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_Low on page 18-554

The MAC Address57 Low register holds the lower 32 bits of the 58th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address58_High on page 18-554

The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address58_Low on page 18-558

The MAC Address58 Low register holds the lower 32 bits of the 59th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address59_High on page 18-558

The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_Low on page 18-562

The MAC Address59 Low register holds the lower 32 bits of the 60th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address60_High on page 18-562

The MAC Address60 High register holds the upper 16 bits of the 61th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address60 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address60_Low on page 18-566

The MAC Address60 Low register holds the lower 32 bits of the 61th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address61_High on page 18-566

The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_Low on page 18-570

The MAC Address61 Low register holds the lower 32 bits of the 62th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address62_High on page 18-570

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_Low on page 18-574

The MAC Address62 Low register holds the lower 32 bits of the 63th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address63_High on page 18-574

The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address63_Low on page 18-578

The MAC Address63 Low register holds the lower 32 bits of the 64th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address64_High on page 18-578

The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_Low on page 18-582

The MAC Address64 Low register holds the lower 32 bits of the 65th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address65_High on page 18-582

The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address65_Low on page 18-586

The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address66_High on page 18-586

The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_Low on page 18-590

The MAC Address66 Low register holds the lower 32 bits of the 67th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address67_High on page 18-590

The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_Low on page 18-594

The MAC Address67 Low register holds the lower 32 bits of the 68th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address68_High on page 18-594

The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_Low on page 18-598

The MAC Address68 Low register holds the lower 32 bits of the 69th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address69_High on page 18-598

The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address69_Low on page 18-602

The MAC Address69 Low register holds the lower 32 bits of the 70th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address70_High on page 18-602

The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_Low on page 18-606

The MAC Address70 Low register holds the lower 32 bits of the 71th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address71_High on page 18-606

The MAC Address71 High register holds the upper 16 bits of the 72th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address71 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address71_Low on page 18-610

The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address72_High on page 18-610

The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address72_Low on page 18-614

The MAC Address72 Low register holds the lower 32 bits of the 73th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address73_High on page 18-614

The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address73_Low on page 18-618

The MAC Address73 Low register holds the lower 32 bits of the 74th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address74_High on page 18-618

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_Low on page 18-622

The MAC Address74 Low register holds the lower 32 bits of the 75th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address75_High on page 18-622

The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_Low on page 18-626

The MAC Address75 Low register holds the lower 32 bits of the 76th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address76_High on page 18-626

The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_Low on page 18-630

The MAC Address76 Low register holds the lower 32 bits of the 77th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address77_High on page 18-630

The MAC Address77 High register holds the upper 16 bits of the 78th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address77 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address77_Low on page 18-634

The MAC Address77 Low register holds the lower 32 bits of the 78th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address78_High on page 18-634

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address78_Low on page 18-638

The MAC Address78 Low register holds the lower 32 bits of the 79th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address79_High on page 18-638

The MAC Address79 High register holds the upper 16 bits of the 80th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address79 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address79_Low on page 18-642

The MAC Address79 Low register holds the lower 32 bits of the 80th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address80_High on page 18-642

The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_Low on page 18-646

The MAC Address80 Low register holds the lower 32 bits of the 81th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address81_High on page 18-646

The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_Low on page 18-650

The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address82_High on page 18-650

The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address82_Low on page 18-654

The MAC Address82 Low register holds the lower 32 bits of the 83th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address83_High on page 18-654

The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_Low on page 18-658

The MAC Address83 Low register holds the lower 32 bits of the 84th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address84_High on page 18-658

The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_Low on page 18-662

The MAC Address84 Low register holds the lower 32 bits of the 85th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address85_High on page 18-662

The MAC Address85 High register holds the upper 16 bits of the 86th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address85 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address85_Low on page 18-666

The MAC Address85 Low register holds the lower 32 bits of the 86th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address86_High on page 18-666

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_Low on page 18-670

The MAC Address86 Low register holds the lower 32 bits of the 87th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address87_High on page 18-670

The MAC Address87 High register holds the upper 16 bits of the 88th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address87 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address87_Low on page 18-674

The MAC Address87 Low register holds the lower 32 bits of the 88th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address88_High on page 18-674

The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_Low on page 18-678

The MAC Address88 Low register holds the lower 32 bits of the 89th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address89_High on page 18-678

The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_Low on page 18-682

The MAC Address89 Low register holds the lower 32 bits of the 90th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address90_High on page 18-682

The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_Low on page 18-686

The MAC Address90 Low register holds the lower 32 bits of the 91th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address91_High on page 18-686

The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address91_Low on page 18-690

The MAC Address91 Low register holds the lower 32 bits of the 92th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address92_High on page 18-690

The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address92_Low on page 18-694

The MAC Address92 Low register holds the lower 32 bits of the 93th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address93_High on page 18-694

The MAC Address93 High register holds the upper 16 bits of the 94th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address93 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address93_Low on page 18-698

The MAC Address93 Low register holds the lower 32 bits of the 94th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address94_High on page 18-698

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_Low on page 18-702

The MAC Address94 Low register holds the lower 32 bits of the 95th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address95_High on page 18-702

The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address95_Low on page 18-706

The MAC Address95 Low register holds the lower 32 bits of the 96th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address96_High on page 18-706

The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_Low on page 18-710

The MAC Address96 Low register holds the lower 32 bits of the 97th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address97_High on page 18-710

The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address97_Low on page 18-714

The MAC Address97 Low register holds the lower 32 bits of the 98th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address98_High on page 18-714

The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_Low on page 18-718

The MAC Address98 Low register holds the lower 32 bits of the 99th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address99_High on page 18-718

The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_Low on page 18-722

The MAC Address99 Low register holds the lower 32 bits of the 100th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address100_High on page 18-722

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_Low on page 18-726

The MAC Address100 Low register holds the lower 32 bits of the 101th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address101_High on page 18-726

The MAC Address101 High register holds the upper 16 bits of the 102th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address101 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address101_Low on page 18-730

The MAC Address101 Low register holds the lower 32 bits of the 102th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address102_High on page 18-730

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_Low on page 18-734

The MAC Address102 Low register holds the lower 32 bits of the 103th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address103_High on page 18-734

The MAC Address103 High register holds the upper 16 bits of the 104th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address103_Low on page 18-738

The MAC Address103 Low register holds the lower 32 bits of the 104th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address104_High on page 18-738

The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_Low on page 18-742

The MAC Address104 Low register holds the lower 32 bits of the 105th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address105_High on page 18-742

The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_Low on page 18-746

The MAC Address105 Low register holds the lower 32 bits of the 106th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address106_High on page 18-746

The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address106_Low on page 18-750

The MAC Address106 Low register holds the lower 32 bits of the 107th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address107_High on page 18-750

The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_Low on page 18-754

The MAC Address107 Low register holds the lower 32 bits of the 108th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address108_High on page 18-754

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_Low on page 18-758

The MAC Address108 Low register holds the lower 32 bits of the 109th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address109_High on page 18-758

The MAC Address109 High register holds the upper 16 bits of the 110th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address109 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address109_Low on page 18-762

The MAC Address109 Low register holds the lower 32 bits of the 110th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address110_High on page 18-762

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_Low on page 18-766

The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address111_High on page 18-766

The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address111_Low on page 18-770

The MAC Address111 Low register holds the lower 32 bits of the 112th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address112_High on page 18-770

The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address112_Low on page 18-774

The MAC Address112 Low register holds the lower 32 bits of the 113th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address113_High on page 18-774

The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_Low on page 18-778

The MAC Address113 Low register holds the lower 32 bits of the 114th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address114_High on page 18-778

The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_Low on page 18-782

The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address115_High on page 18-782

The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address115_Low on page 18-786

The MAC Address115 Low register holds the lower 32 bits of the 116th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address116_High on page 18-786

The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_Low on page 18-790

The MAC Address116 Low register holds the lower 32 bits of the 117th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address117_High on page 18-790

The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address117_Low on page 18-794

The MAC Address117 Low register holds the lower 32 bits of the 118th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address118_High on page 18-794

The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_Low on page 18-798

The MAC Address118 Low register holds the lower 32 bits of the 119th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address119_High on page 18-798

The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_Low on page 18-802

The MAC Address119 Low register holds the lower 32 bits of the 120th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address120_High on page 18-802

The MAC Address120 High register holds the upper 16 bits of the 121th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_Low on page 18-806

The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address121_High on page 18-806

The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_Low on page 18-810

The MAC Address121 Low register holds the lower 32 bits of the 122th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address122_High on page 18-810

The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address122_Low on page 18-814

The MAC Address122 Low register holds the lower 32 bits of the 123th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address123_High on page 18-814

The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_Low on page 18-818

The MAC Address123 Low register holds the lower 32 bits of the 124th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address124_High on page 18-818

The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_Low on page 18-822

The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address125_High on page 18-822

The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low on page 18-826

The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address126_High on page 18-826

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address126_Low on page 18-830

The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address127_High on page 18-830

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_Low on page 18-834

The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700000
emac1	0xFF702000	0xFF702000

Offset: 0x0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Configuration Fields

Bit	Name	Description	Access	Reset						
27	twokpe	When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.	RW	0x0						
25	cst	When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Strip Ether Frames Off</td></tr> <tr> <td>0x1</td><td>Strip Ether Frames On</td></tr> </tbody> </table>	Value	Description	0x0	Strip Ether Frames Off	0x1	Strip Ether Frames On	RW	0x0
Value	Description									
0x0	Strip Ether Frames Off									
0x1	Strip Ether Frames On									
24	tc	When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII. When this bit is reset, no such information is driven to the PHY. <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x1</td><td>Enables Transmission of duplex</td></tr> <tr> <td>0x0</td><td>Disables Transmission to Phy</td></tr> </tbody> </table>	Value	Description	0x1	Enables Transmission of duplex	0x0	Disables Transmission to Phy	RW	0x0

Bit	Name	Description	Access	Reset						
4	dc	<p>When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Deferral Check Enabled</td> </tr> <tr> <td>0x0</td> <td>Deferral Check Disabled</td> </tr> </tbody> </table>	Value	Description	0x1	Deferral Check Enabled	0x0	Deferral Check Disabled	RW	0x0

MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700004
emac1	0xFF702000	0xFF702004

Offset: 0x4

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset
15:0	gd	This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the gb bit (busy bit) of the GMII_Address register set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The gb bit of the GMII_Address register remains set until the control frame is transferred onto the cable. The Host must make sure that the gb bit is cleared before writing to the register.

0x0	Enable Auto Gen. of Zero-Quanta Pause									

Bit	Name	Description	Access	Reset										
5:4	plt	<p>This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Pause time - 4 slot times</td> </tr> <tr> <td>0x1</td> <td>Pause time - 28 slot times</td> </tr> <tr> <td>0x2</td> <td>Pause time - 144 slot times</td> </tr> <tr> <td>0x3</td> <td>Pause time - 256 slot times</td> </tr> </tbody> </table>	Value	Description	0x0	Pause time - 4 slot times	0x1	Pause time - 28 slot times	0x2	Pause time - 144 slot times	0x3	Pause time - 256 slot times	RW	0x0
Value	Description													
0x0	Pause time - 4 slot times													
0x1	Pause time - 28 slot times													
0x2	Pause time - 144 slot times													
0x3	Pause time - 256 slot times													
3	up	<p>When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>MAC Detects Pause MCA</td> </tr> <tr> <td>0x1</td> <td>MAC Detects Pause MCA and UCA</td> </tr> </tbody> </table>	Value	Description	0x0	MAC Detects Pause MCA	0x1	MAC Detects Pause MCA and UCA	RW	0x0				
Value	Description													
0x0	MAC Detects Pause MCA													
0x1	MAC Detects Pause MCA and UCA													
2	rfe	<p>When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Decode Func. of Pause Frame Disabled</td> </tr> <tr> <td>0x1</td> <td>MAC decodes the received Pause</td> </tr> </tbody> </table>	Value	Description	0x0	Decode Func. of Pause Frame Disabled	0x1	MAC decodes the received Pause	RW	0x0				
Value	Description													
0x0	Decode Func. of Pause Frame Disabled													
0x1	MAC decodes the received Pause													

Bit	Name	Description	Access	Reset						
1	tfe	<p>In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmit Flow Control Disable</td> </tr> <tr> <td>0x1</td> <td>Transmit Flow Control Enable</td> </tr> </tbody> </table>	Value	Description	0x0	Transmit Flow Control Disable	0x1	Transmit Flow Control Enable	RW	0x0
Value	Description									
0x0	Transmit Flow Control Disable									
0x1	Transmit Flow Control Enable									
0	fca_bpa	<p>This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Pause Ctrl Frame and BPA off</td> </tr> <tr> <td>0x1</td> <td>Init Pause Ctrl Frame and BPA</td> </tr> </tbody> </table>	Value	Description	0x0	Pause Ctrl Frame and BPA off	0x1	Init Pause Ctrl Frame and BPA	RW	0x0
Value	Description									
0x0	Pause Ctrl Frame and BPA off									
0x1	Init Pause Ctrl Frame and BPA									

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF70001C
emac1	0xFF702000	0xFF70201C

Offset: 0x1C

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

VLAN_Tag Fields

Bit	Name	Description	Access	Reset
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0

Bit	Name	Description	Access	Reset						
16	etv	<p>When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disable 12-Bit VLAN Tag Compare</td> </tr> <tr> <td>0x1</td> <td>Enable 12-Bit VLAN Tag Compare</td> </tr> </tbody> </table>	Value	Description	0x0	Disable 12-Bit VLAN Tag Compare	0x1	Enable 12-Bit VLAN Tag Compare	RW	0x0
Value	Description									
0x0	Disable 12-Bit VLAN Tag Compare									
0x1	Enable 12-Bit VLAN Tag Compare									
15:0	vl	<p>This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.</p>	RW	0x0						

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Bit	Name	Description	Access	Reset
15:8	userver	Altera-defined Version	RO	0x10
7:0	snpsver	Synopsys-defined Version (3.7)	RO	0x37

Debug

The Debug register gives the status of all main blocks of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700024
emac1	0xFF702000	0xFF702024

Offset: 0x24

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset						
19	lpitxa	<p>This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>LPI TX Automate Disabled</td> </tr> <tr> <td>0x1</td> <td>LPI TX Automate Enabled</td> </tr> </tbody> </table>	Value	Description	0x0	LPI TX Automate Disabled	0x1	LPI TX Automate Enabled	RW	0x0

0x1	MAC Transmitter Entered LPI State									

LPI_Timers_Control

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700034
emac1	0xFF702000	0xFF702034

Offset: 0x34

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

LPI_Timers_Control Fields

Bit	Name	Description	Access	Reset
25:16	lst	This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	twl	This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Module Instance	Base Address	Register Address

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with

0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700040
emac1	0xFF702000	0xFF702040

Offset: 0x40

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address3_High

The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700058
emac1	0xFF702000	0xFF702058

Offset: 0x58

MAC_Address5_High

The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700068

MAC_Address11_High

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address13_High

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF7000A8
emac1	0xFF702000	0xFF7020A8

Offset: 0xA8

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address15_Low

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700100
emac1	0xFF702000	0xFF702100

MMC_Control Fields

Bit	Name	Description	Access	Reset
8	ucdbc	When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0

Bit	Name	Description	Access	Reset						
5	cntprstlvl	<p>When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFFF0.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Preset All Counters to almost-half</td> </tr> <tr> <td>0x1</td> <td>Present All Counters almost-full</td> </tr> </tbody> </table>	Value	Description	0x0	Preset All Counters to almost-half	0x1	Present All Counters almost-full	RW	0x0
Value	Description									
0x0	Preset All Counters to almost-half									
0x1	Present All Counters almost-full									
4	cntprst	<p>When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Counters not preset</td> </tr> <tr> <td>0x1</td> <td>Counters preset to full or almost full</td> </tr> </tbody> </table>	Value	Description	0x0	Counters not preset	0x1	Counters preset to full or almost full	RW	0x0
Value	Description									
0x0	Counters not preset									
0x1	Counters preset to full or almost full									
3	cntfreez	<p>When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Update MMC Counters</td> </tr> <tr> <td>0x1</td> <td>Freeze MMC counters to current value</td> </tr> </tbody> </table>	Value	Description	0x0	Update MMC Counters	0x1	Freeze MMC counters to current value	RW	0x0
Value	Description									
0x0	Update MMC Counters									
0x1	Freeze MMC counters to current value									

Bit	Name	Description	Access	Reset						
2	rstonrd	<p>When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No reset after read</td> </tr> <tr> <td>0x1</td> <td>Reset after read</td> </tr> </tbody> </table>	Value	Description	0x0	No reset after read	0x1	Reset after read	RW	0x0
Value	Description

This bit is cleared automatically after one clock cycle.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Auto cleared after 1 clock cycle</td> </tr> <tr> <td>0x1</td> <td>All Counters Reset</td> </tr> </tbody> </table>	Value	Description	0x0	Auto cleared after 1 clock cycle	0x1	All Counters Reset	RW	0x0
Value	Description									
0x0	Auto cleared after 1 clock cycle									
0x1	All Counters Reset									

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700104
emac1	0xFF702000	0xFF702104

Offset: 0x104

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MMC_Transmit_Interrupt

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700108
emac1	0xFF702000	0xFF702108

Offset: 0x108

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MMC_Transmit_Interrupt_Mask

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700110
emac1	0xFF702000	0xFF702110

Offset: 0x110

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700208
emac1	0xFF702000	0xFF702208

Offset: 0x208

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Sub_Second_Increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700704
emac1	0xFF702000	0xFF702704

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

		execution of this command. * 0111-1111: Reserved		

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

ppsint RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ppsint RW 0x0															

PPS0_Interval Fields

Bit	Name	Description	Access	Reset
31:0	ppsint	These bits store the interval between the rising edges of PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS0 signal output is 100ns (that is, five units of sub-second increment value), then you should program value 4 (5 -1) in this register.	RW	0x0

PPS0_Width

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700764
emac1	0xFF702000	0xFF702764

Offset: 0x764

Access: RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ppswidth RW 0x0															

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	ppswidth	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	RW	0x0

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address19_High

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700818
emac1	0xFF702000	0xFF702818

31:0	addrlo	This field contains the lower 32 bits of the 21th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address21_High

The MAC Address21 High register holds the upper 16 bits of the 22th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700828
emac1	0xFF702000	0xFF702828

Offset: 0x828

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address27_High

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700858
emac1	0xFF702000	0xFF702858

MAC_Address29_High

The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700868
emac1	0xFF702000	0xFF702868

Offset: 0x868

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

31:0	addrlo	This field contains the lower 32 bits of the 38th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address38_High

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF7008B0
emac1	0xFF702000	0xFF7028B0

Offset: 0x8B0

MAC_Address40_High

The MAC Address40 High register holds the upper 16 bits of the 41th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 46th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address46_High

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF7008F0
emac1	0xFF702000	0xFF7028F0

Offset: 0x8F0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address54_High

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address56_High

The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_High

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700970
emac1	0xFF702000	0xFF702970

Offset: 0x970

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

31:0	addrlo	This field contains the lower 32 bits of the 64th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address64_High

The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700980
emac1	0xFF702000	0xFF702980

Offset: 0x980

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address73_High

The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_High

The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_High

The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

31:0	addrlo	This field contains the lower 32 bits of the 91th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address91_High

The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700A58
emac1	0xFF702000	0xFF702A58

Offset: 0xA58

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

MAC_Address94_High

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_High

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_High

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

31:0	addrlo	This field contains the lower 32 bits of the 116th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address116_High

The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700B20
emac1	0xFF702000	0xFF702B20

Offset: 0xB20

MAC_Address124_High

The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address126_High

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700B70
emac1	0xFF702000	0xFF702B70

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

Bus_Mode on page 18-836

The Bus Mode register establishes the bus operating modes for the DMA.

Transmit_Poll_Demand on page 18-841

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Receive_Poll_Demand on page 18-842

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Descriptor_List_Address on page 18-843

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 18-844

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 18-845

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 18-850

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 18-857

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 18-861

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 18-863

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 18-863

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 18-866

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Current_Host_Transmit_Descriptor on page 18-867

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 18-868

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 18-868

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 18-869

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 18-870

This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701000
emac1	0xFF702000	0xFF703000

Offset: 0x1000

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset
13:8	pbl	These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.	RW	0x1

Bit	Name	Description	Access	Reset						
7	atds	<p>Alternate Descriptor Size</p> <p>This bit is valid (read or write with default value of 0) when you select the Alternate Descriptor feature and any (or both) of the following features:</p> <ul style="list-style-type: none"> Advanced Timestamp IPC Full Checksum Offload Engine (Type 2) <p>When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). The software application must set this bit when timestamping is enabled in Register 448 (Timestamp Control Register) or Checksum Offload is enabled in Register 0 (MAC Configuration Register). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory.</p> <p>When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Descriptor size is 16 bytes (4 DWORDS)</td> </tr> <tr> <td>0x1</td> <td>Descriptor size is 32 bytes (8 DWORDS)</td> </tr> </tbody> </table>	Value	Description	0x0	Descriptor size is 16 bytes (4 DWORDS)	0x1	Descriptor size is 32 bytes (8 DWORDS)	RW	0x0

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Transmit_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Module Instance	Base Address	Register Address

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address

Receive_Descriptor_List_Address Fields

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address

Status

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10,240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0

Bit	Name	Description	Access	Reset
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701018
emac1	0xFF702000	0xFF703018

Offset: 0x1018

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset										
13	st	<p>When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmission Stopped State</td> </tr> <tr> <td>0x1</td> <td>Transmission in Run State</td> </tr> </tbody> </table>	Value	Description	0x0	Transmission Stopped State	0x1	Transmission in Run State	RW	0x0

Bit	Name	Description	Access	Reset						
1	sr	<p>When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Rx DMA operation is stopped</td> </tr> <tr> <td>0x1</td> <td>Rx DMA operation is started</td> </tr> </tbody> </table>	Value	Description	0x0	Rx DMA operation is stopped	0x1	Rx DMA operation is started	RW	0x0
Value	Description									
0x0	Rx DMA operation is stopped									
0x1	Rx DMA operation is started									

Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF70101C
emac1	0xFF702000	0xFF70301C

Offset: 0x101C

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of

buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701020
emac1	0xFF702000	0xFF703020

Offset: 0x1020

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Missed_Frame_And_Buffer_Overflow_Counter Fields

Bit	Name	Description	Access	Reset
28	ovfcntovf	Overflow bit for FIFO Overflow Counter	RO	0x0
27:17	ovffrmcnt	This field indicates the number of frames missed by the application. This counter is incremented each time the MTL asserts the sideband signal mtl_rxoverflow_o. The counter is cleared when this register is read with mci_be_i[2] at 1'b1.	RO	0x0
16	misctovf	Overflow bit for Missed Frame Counter	RO	0x0
15:0	misfrmcnt	This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read with mci_be_i[0] at 1'b1.	RO	0x0

Receive_Interrupt_Watchdog_Timer

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701024
emac1	0xFF702000	0xFF703024

Offset: 0x1024

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								riwt RW 0x0							

Receive_Interrupt_Watchdog_Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock (14_sys_free_clk) cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701028
emac1	0xFF702000	0xFF703028

Offset: 0x1028

Send Feedback

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys^(†) DesignWare Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Can operate in Host or Device mode
- Supports multi-point applications with hub and split support
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.

- Integrated scatter-gather DMA supports moving data between memory and the controller
- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
 - Control transfers
 - Bulk transfers
 - Isochronous transfers
 - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.

- Supports up to 16 bidirectional endpoints, including control endpoint 0

Note: Only seven periodic device IN endpoints are supported.

- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- 8-bit ULPI PHY data width
- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
 - PHY clock gating support
 - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

PHYs that support LPM mode may not function properly with the USB controller due to a timing issue. It is recommended that designers use the MicroChip USB3300 PHY device that has been proven to be successful on the development board.

Refer to the *Cyclone V Device Datasheet* for specific timing information.

USB OTG Controller Block Diagram and System Integration

Figure 19-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.

The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB controller will only use Direct Shared IO 48.

USB 2.0 ULPI PHY Signal Description

Table 19-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

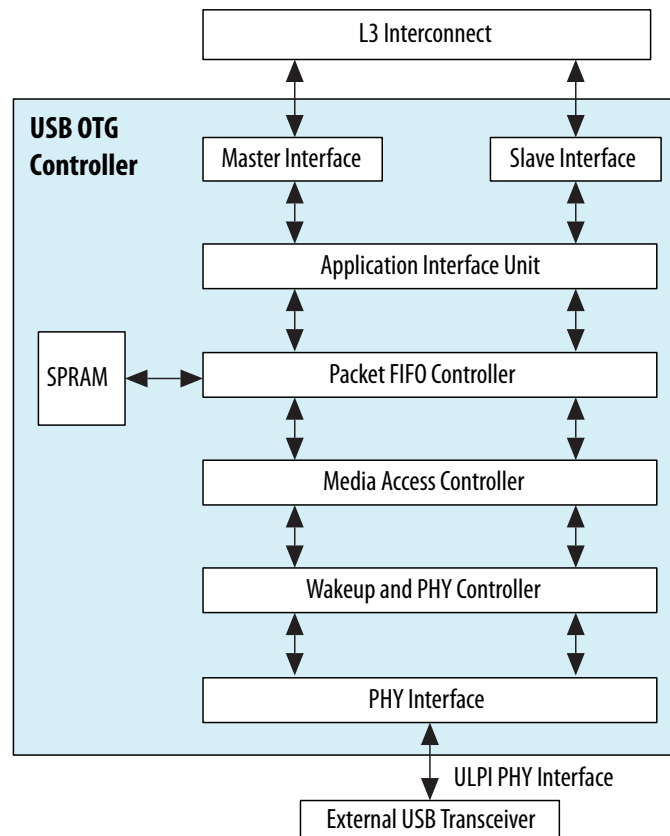

Port Name	Bit Width	Direction	Description
<code>ulpi_clk</code>	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
<code>ulpi_dir</code>	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
<code>ulpi_nxt</code>	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
<code>ulpi_stp</code>	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
<code>ulpi_data[7:0]</code>	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 19-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.

Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the single port RAM (SPRAM).

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (*en*) bit in the USB0 or USB1 RAM ECC Enable Register (*usb0* or *usb1*), in the ECC Management Register Group (*eccgrp*). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

DMA

The DMA has two modes of operation. You program your software to select between scatter-gather DMA mode or buffer DMA mode depending on the controllers function.

If the controller is functioning as a generic root hub, you should program your software to select the buffer DMA mode that supports split transfers.

If generic root hub functionality is not required, or if the controller is configured in Device mode, you can program your software to select scatter-gather DMA mode.

If you wish to dynamically switch the mode of operation based on the queried device status or capability, your software driver must cleanly switch between the two modes of operation. For example, you may want the controller to default to scatter-gather DMA mode and only change mode when it detects a generic HUB with fast-speed and low-speed capability. Some basic requirements for switching include:

- A soft reset must be issued before changing modes.
- If buffer DMA mode is selected, then the Host mode periodic request queue depth must not be set to 16.
- Devices must be re-enumerated.

Local Memory Buffer

The USB controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128×32 -bit memory (512 total bytes)
- The read FIFO buffer is a 32×32 -bit memory (128 total bytes)
- The ECC buffer is a 96×16 -bit memory (1536 total bytes)

The SPRAM is a 8192×35 -bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 19-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the `ulpi_clk` clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the `ulpi_stp` signal. The PHY outputs a clock when it sees the `ulpi_stp` signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the `ulpi_stp` signal. As a result, the `ulpi_clk` clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two `usb_mp_clk` cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.
