After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Table 19-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode

Condition	Mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts

Condition	Mode
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling ECC

1. Turn on the ECC hardware, but disable the interrupts.
2. Initialize the SRAM in the peripheral.⁽⁵⁹⁾
3. Clear the ECC event bits, because these bits may have become asserted after Step 1.
4. Enable the ECC interrupts now that the ECC bits have been set.

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

⁽⁵⁹⁾ This is the case for the following peripherals: SD/MMC, NAND, On-Chip, DMA, USB, and EMAC.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtppwr`) bit to 1 in the Host Port Control and Status Register (`hprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

The controller waits for a connection to be detected on the USB link.

2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDet`) bit in `hprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtENCHng`) and Port Speed (`prtspd`) bits, in `hprt`, are set to reflect the enumerated speed of the device that attached.

At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`hostgrp`) group.

7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:
 - a. Receive FIFO Size Register (`grxfsiz`)—selects the size of the receive FIFO buffer
 - b. Non-periodic Transmit FIFO Size Register (`gnptxfsiz`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
 - c. Host Periodic Transmit FIFO Size Register (`hptxfsiz`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dcfg`) in the Device Mode Registers (`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.
2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received

on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

When an isochronous IN endpoint has more than one transaction (or packet) per micro-frame, it is referred to as a high-bandwidth isochronous endpoint. This endpoint should follow the Data PID sequencing specified in section 5.9.2 of the USB 2.0 Specification. This will allow the device controller to support a maximum of three transactions per micro-frame and high-bandwidth isochronous IN endpoints in the Ignore Frame Number mode of the device descriptor DMA configuration.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

According to the USB 2.0 specifications, to transmit two packets back-to-back, the inter-packet delay must be a minimum of 88 bit times, measured at the first receptacle of the host. This will guarantee an inter-packet delay of at least 32 bit times at all devices (when receiving these back-to-back packets). For the device controller to support the worst-case inter-packet delay of 32 bit times and isochronous OUT endpoints across multiple layers of hubs, the controller must operate in 8-bit UTMI mode and the AHB frequency must be at least 96 MHz.

Alternatively, choose the AHB clock frequency based on your targeted use case and supported number of hubs. However, in both cases the 8-bit PHY data interface should be used for operation using the SoC.

Table 19-4: Supported Number of Hubs Tiers for Different PHY and AHB Clock Frequencies

Number of Hub Levels	Worst Case IPG Possible at Hub/Host Downstream Port (in bit times)	Minimum HCLK Frequency Required (in MHz)	
		UTMI Data Width = 8	UTMI Data Width = 16
No Hub	88	30	110
1	78.4	32	213
2	68.8	37	-
3	59.2	44	-
4	49.6	54	-
5	40	70	-

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB 2.0 OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consists of the following region:

USB OTG Controller Module Registers Address Map on page 19-17

Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

Related Information

- **Introduction to the Hard Processor System** on page 2-1
The base addresses of all modules are listed in the *Introduction to the Hard Processor System* chapter.

Direct_FIFO	This address space is allocated for directly accessing the data FIFO for debugging purposes.	0x20000	0x3FFFF

Global Registers Register Descriptions

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Offset: 0x0

[gotgctl](#) on page 19-41

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

[gotgint](#) on page 19-46

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

[gahbcfg](#) on page 19-48

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

gusbcfg on page 19-53

This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

grstctl on page 19-58

The application uses this register to reset various hardware features inside the core

gintsts on page 19-63

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk on page 19-73

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstr on page 19-78

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsp on page 19-80

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxfsiz on page 19-81

The application can program the RAM size that must be allocated to the Rx FIFO.

gnptxsiz on page 19-82

The application can program the RAM size and the memory start address for the Non-periodic Tx FIFO. The fields of this register change, depending on host or device mode.

gnptxsts on page 19-83

In Device mode, this register is valid only in Shared FIFO operation. It contains the free space information for the Non-periodic Tx FIFO and the Nonperiodic Transmit Request Queue

gpvndctl on page 19-84

The application can use this register to access PHY registers. for a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access

ggpio on page 19-86

The application can use this register for general purpose input/output ports or for debugging.

guid on page 19-87

This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

gsnpsid on page 19-88

This read-only register contains the release number of the core being used.

ghwcfg1 on page 19-89

This register contains the logical endpoint direction(s).

ghwcfg2 on page 19-89

This register contains configuration options.

ghwcfg3 on page 19-94

This register contains the configuration options.

ghwcfg4 on page 19-96

This register contains the configuration options.

gdfifocfg on page 19-101

Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

hptxsiz on page 19-102

This register holds the size and the memory start address of the Periodic TxFIFO

dieptxf1 on page 19-102

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf2 on page 19-103

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf3 on page 19-104

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf4 on page 19-105

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf5 on page 19-106

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf6 on page 19-107

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf7 on page 19-107

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf8 on page 19-108

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf9 on page 19-109

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf10 on page 19-110

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf11 on page 19-111

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf12 on page 19-112

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf13 on page 19-112

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf14 on page 19-113

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf15 on page 19-114

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

gotgctl

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00000
usb1	0xFFB40000	0xFFB40000

Offset: 0x0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

2:0	toutcal	Mode:Host and Device. The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: -One 30-MHz PHY clock = 16 bit times -One 60-MHz PHY clock = 8 bit times Full-speed operation: -One 30-MHz PHY clock = 0.4 bit times -One 60-MHz PHY clock = 0.2 bit times -One 48-MHz PHY clock = 0.25 bit times	RW	0x0				

grstctl

The application uses this register to reset various hardware features inside the core

Bit	Name	Description	Access	Reset						
5	txfflsh	<p>Mode:Host and Device. This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is notreading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writinganything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.</p> <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Flush</td> </tr> <tr> <td>0x1</td> <td>selectively flushes a single or all transmit FIFOs</td> </tr> </tbody> </table> <p>Note: You can also flush the TXFIFO when the phy_clk (internally generated) is turned off and hclk (14_mp_clk) is turned on.</p>	Value	Description	0x0	No Flush	0x1	selectively flushes a single or all transmit FIFOs	RO	0x0
Value	Description									
0x0	No Flush									
0x1	selectively flushes a single or all transmit FIFOs									
4	rxfflsh	<p>Mode:Host and Device. The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.</p> <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no flush the entire RxFIFO</td> </tr> <tr> <td>0x1</td> <td>flush the entire RxFIFO</td> </tr> </tbody> </table>	Value	Description	0x0	no flush the entire RxFIFO	0x1	flush the entire RxFIFO	RO	0x0

Bit	Name	Description	Access	Reset						
0	csftrst	<p>Mode:Host and Device. Resets the hclk and phy_ clock domains as follows:Clears the interrupts and all the CSR registers except the following register bits: - PCGCCTL.RstPdownModule - PCGCCTL.GateHclk - PCGCCTL.PwrClmp - PCGCCTL.StopPPhyLPwrClkSelclk - GUSBCFG.PhyLPwrClkSel - GUSBCFG.DDRSel - GUSBCFG.PHYSel - GUSBCFG.FSIntf - GUSBCFG.ULPI_UTMI_Sel - GUSBCFG.PHYIf - HCFG.FSLSPclkSel - DCFG.DevSpd - GGPIO - GPWRDN - GADPCTL All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. Any transactions on the AHB Master are terminated as soonas possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No reset</td> </tr> <tr> <td>0x1</td> <td>Resets hclk and phy_clock domains</td> </tr> </tbody> </table>	Value	Description	0x0	No reset	0x1	Resets hclk and phy_clock domains	RO	0x0
Value	Description									
0x0	No reset									
0x1	Resets hclk and phy_clock domains									

gintsts

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00014
usb1	0xFFB40000	0xFFB40014

Offset: 0x14

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

3	sof	<p>Mode: Host and Device. In Host mode, the core sets this bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In Device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. This bit can be set only by the core and the application should write 1 to clear it. This register may return 1 if read immediately after power on reset. If the register bit reads 1 immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No sof</td> </tr> <tr> <td>0x1</td> <td>Start of Frame</td> </tr> </tbody> </table>	Value	Description	0x0	No sof	0x1	Start of Frame	RO	0x0
Value	Description

gintmsk

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

Module Instance	Base Address	Register Address

grxstsr

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

Host Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Host mode.

Offset: 0x400

hcfg on page 19-125

Host Mode control. This register must be programmed every time the core changes to Host mode

hfir on page 19-128

This register stores the frame interval information for the current speed to which the otg core has enumerated

hfnm on page 19-129

This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue

hptxsts on page 19-130

This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue.

haint on page 19-133

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

haintmsk on page 19-134

The Host All Channel Interrupt Mask register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

hflbaddr on page 19-135

This Register is valid only for Host mode Scatter-Gather DMA. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.

hpri on page 19-136

This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

hcchar0 on page 19-140

Channel_number: 0.

hcsplt0 on page 19-143

Channel_number 0

hcint0 on page 19-145

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk0 on page 19-149

This register reflects the mask for each channel status described in the previous section.

hctsiz0 on page 19-151

Buffer DMA Mode

hcdma0 on page 19-152

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab0 on page 19-153

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar1 on page 19-154

Host Channel 1 Characteristics Register

hcsplt1 on page 19-157

Channel_number 1

hcint1 on page 19-159

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk1 on page 19-163

This register reflects the mask for each channel status described in the previous section.

hctsiz1 on page 19-165

Buffer DMA Mode

hcdma1 on page 19-166

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab1 on page 19-168

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar2 on page 19-168

Host Channel 2 Characteristics Register

hcsplt2 on page 19-171

Channel_number 2

hcint2 on page 19-173

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk2 on page 19-177

This register reflects the mask for each channel status described in the previous section.

hctsiz2 on page 19-179

Buffer DMA Mode.

hcdma2 on page 19-180

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab2 on page 19-182

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar3 on page 19-182

Channel_number: 3.

hcsplt3 on page 19-185

Channel_number 3

hcint3 on page 19-187

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk3 on page 19-191

This register reflects the mask for each channel status described in the previous section.

hctsiz3 on page 19-193

Buffer DMA Mode

hcdma3 on page 19-194

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab3 on page 19-196

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar4 on page 19-196

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcsplt4 on page 19-197

Channel_number 4

hcint4 on page 19-199

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk4 on page 19-203

This register reflects the mask for Channel 4 interrupt status bits.

hctsiz4 on page 19-205

Buffer DMA Mode Channel 4

hcdma4 on page 19-206

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab4 on page 19-207

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

Channel_number: 5.

hcsplt5 on page 19-212

Channel_number 5

hcint5 on page 19-214

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk5 on page 19-218

This register reflects the mask for each channel status described in the previous section.

hctsiz5 on page 19-220

Buffer DMA Mode

hcdma5 on page 19-221

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab5 on page 19-222

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar6 on page 19-223

Host Channel 6 Characteristics Register

hcsplt6 on page 19-226

Channel_number 6

hcint6 on page 19-228

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk6 on page 19-232

This register reflects the mask for each channel status described in the previous section.

hctsiz6 on page 19-234

Buffer DMA Mode

hcdma6 on page 19-235

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab6 on page 19-237

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar7 on page 19-237

Host Channel 7 Characteristics Register

hcsplt7 on page 19-240

Channel_number 7

hcint7 on page 19-242

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk7 on page 19-246

This register reflects the mask for each channel status described in the previous section.

hctsiz7 on page 19-248

Buffer DMA Mode

hcdma7 on page 19-249

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab7 on page 19-251

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar8 on page 19-251

Host Channel 8 Characteristics Register

hcsplt8 on page 19-254

Channel_number 8

hcint8 on page 19-256

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

haint

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00414
usb1	0xFFB40000	0xFFB40414

Offset: 0x414

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

31:0	hflbaddr	This Register is valid only for Host mode Scatter-Gather DMA mode. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.	RW	0x0

hprt

This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00440
usb1	0xFFB40000	0xFFB40440

Offset: 0x440

Bit	Name	Description	Access	Reset						
7	prtsusp	<p>The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is Set. To stop the PHY clock, the application must Set the Port Clock Stop bit, which asserts the suspend input pin of the PHY. The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the Port Reset bit or Port Resume bit in this register or the Resume/Remote Wakeup Detected Interrupt bit or Disconnect Detected Interrupt bit in the Core Interrupt register (GINTSTS.WkUpInt or GINTSTS.DisconnInt, respectively). This bit is cleared by the core even if there is no device connected to the Host.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Port not in Suspend mode</td> </tr> <tr> <td>0x1</td> <td>Port in Suspend mode</td> </tr> </tbody> </table>	Value	Description	0x0	Port not in Suspend mode	0x1	Port in Suspend mode	RO	0x0
Value	Description									
0x0	Port not in Suspend mode									
0x1	Port in Suspend mode									
6	prtres	<p>The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the Port Resume/Remote Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.WkUpInt), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling. When LPM is enabled and the core is in the L1 (Sleep) state, setting this bit results in the following behavior: The core continues to drive the resume signal until a pre-determined time specified in the GLPMCFG.HIRD_Thres[3:0] field. If the core detects a USB remote wakeup sequence, as indicated by the Port L1 Resume/Remote L1 Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.L1WkUpInt), the core starts driving resume signaling without application intervention and clears this bit at the end of the resume. The read value of this bit indicates whether the core is currently driving resume signaling.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No resume driven</td> </tr> <tr> <td>0x1</td> <td>Resume driven</td> </tr> </tbody> </table>	Value	Description	0x0	No resume driven	0x1	Resume driven	RW	0x0

hcint0

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

31	chena	<p>When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 0: Channel disabled 1: Channel enabled When Scatter/Gather mode is enabled.</p> <table border="0"> <tr> <td>Value</td><td>Description</td> </tr> <tr> <td>0x0</td><td>Indicates that the descriptor structure is not yet ready</td> </tr> <tr> <td>0x1</td><td>Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor</td> </tr> </table>	Value	Description	0x0	Indicates that the descriptor structure is not yet ready	0x1	Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor	RO	0x0
Value	Description									
0x0	Indicates that the descriptor structure is not yet ready									
0x1	Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor									
30	chdis	<p>The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel Disabled interrupt before treating the channel as disabled.</p> <table border="0"> <tr> <td>Value</td><td>Description</td> </tr> <tr> <td>0x0</td><td>Transmit/Recieve normal</td> </tr> <tr> <td>0x1</td><td>Stop transmitting/receiving</td> </tr> </table>	Value	Description	0x0	Transmit/Recieve normal	0x1	Stop transmitting/receiving	RO	0x0
Value	Description									
0x0	Transmit/Recieve normal									
0x1	Stop transmitting/receiving									
28:22	devaddr	This field selects the specific device serving as the data source or sink.	RW	0x0						

Bit	Name	Description	Access	Reset										
21:20	ec	<p>When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (0), this field indicates to the host the number of transactions that must be executed per microframe for this periodic endpoint. for non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched for this channel before the internal DMA engine changes arbitration. When HCSPLTn.SpltEna is Set (1), this field indicates the number of immediate retries to be performed for a periodic split transactions on transaction errors. This field must be set to at least 1.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Reserved This field yields undefined result</td> </tr> <tr> <td>0x1</td> <td>1 transaction</td> </tr> <tr> <td>0x2</td> <td>2 transactions to be issued for this endpoint per microframe</td> </tr> <tr> <td>0x3</td> <td>3 transactions to be issued for this endpoint per microframe</td> </tr> </tbody> </table>	Value	Description	0x0	Reserved This field yields undefined result	0x1	1 transaction	0x2	2 transactions to be issued for this endpoint per microframe	0x3	3 transactions to be issued for this endpoint per microframe	RW	0x0
Value	Description													
0x0	Reserved This field yields undefined result													
0x1	1 transaction													
0x2	2 transactions to be issued for this endpoint per microframe													
0x3	3 transactions to be issued for this endpoint per microframe													
19:18	eptype	<p>Indicates the transfer type selected.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Control</td> </tr> <tr> <td>0x1</td> <td>Isochronous</td> </tr> <tr> <td>0x2</td> <td>Bulk</td> </tr> <tr> <td>0x3</td> <td>Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	Control	0x1	Isochronous	0x2	Bulk	0x3	Interrupt	RW	0x0
Value	Description													
0x0	Control													
0x1	Isochronous													
0x2	Bulk													
0x3	Interrupt													
17	lspddev	<p>This field is set by the application to indicate that this channel is communicating to a low-speed device. The application must program this bit when a low speed device is connected to the host through an FS HUB. The HS OTG Host core uses this field to drive the XCVR_SELECT signal to 0x3 while communicating to the LS Device through the FS hub. In a peer to peer setup, the HS OTG Host core ignores this bit even if it is set by the application software</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Communicating with low speed device</td> </tr> <tr> <td>0x1</td> <td>Communicating with low speed device</td> </tr> </tbody> </table>	Value	Description	0x0	Not Communicating with low speed device	0x1	Communicating with low speed device	RW	0x0				
Value	Description													
0x0	Not Communicating with low speed device													
0x1	Communicating with low speed device													

Bit	Name	Description	Access	Reset																																		
15	epdir	Indicates whether the transaction is IN or OUT. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>OUT Direction</td> </tr> <tr> <td>0x1</td> <td>IN Direction</td> </tr> </tbody> </table>	Value	Description	0x0	OUT Direction	0x1	IN Direction	RW	0x0																												
Value	Description																																					
0x0	OUT Direction																																					
0x1	IN Direction																																					
14:11	epnum	Indicates the endpoint number on the device serving as the data source or sink. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr><td>0x0</td><td>End point 0</td></tr> <tr><td>0x1</td><td>End point 1</td></tr> <tr><td>0x2</td><td>End point 2</td></tr> <tr><td>0x3</td><td>End point 3</td></tr> <tr><td>0x4</td><td>End point 4</td></tr> <tr><td>0x5</td><td>End point 5</td></tr> <tr><td>0x6</td><td>End point 6</td></tr> <tr><td>0x7</td><td>End point 7</td></tr> <tr><td>0x8</td><td>End point 8</td></tr> <tr><td>0x9</td><td>End point 9</td></tr> <tr><td>0xa</td><td>End point 10</td></tr> <tr><td>0xb</td><td>End point 11</td></tr> <tr><td>0xc</td><td>End point 12</td></tr> <tr><td>0xd</td><td>End point 13</td></tr> <tr><td>0xe</td><td>End point 14</td></tr> <tr><td>0xf</td><td>End point 15</td></tr> </tbody> </table>	Value	Description	0x0	End point 0	0x1	End point 1	0x2	End point 2	0x3	End point 3	0x4	End point 4	0x5	End point 5	0x6	End point 6	0x7	End point 7	0x8	End point 8	0x9	End point 9	0xa	End point 10	0xb	End point 11	0xc	End point 12	0xd	End point 13	0xe	End point 14	0xf	End point 15	RW	0x0

6:0	prtaddr	This field is the port number of the recipient transaction translator.	RW	0x0										

hcint1

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

hcdma1 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma1	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab1

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint2

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

0x2	DATA1													
0x3	MDATA (non-control)/SETUP (control)													
28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										
18:0	xfersize	<p>for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.</p>	RW	0x0										

hcdma2

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma2 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma2	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab2

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint3

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma3 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma3	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab3

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint4

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

0x3	MDATA (non-control)/SETUP (control)													
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0										
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.	RW	0x0										

hcdma4

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma4 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma4	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N]</p> <p>Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab4

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint5

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma5 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma5	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2^{*(nTD+1)}$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N]</p> <p>Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab5

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint6

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma6 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma6	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N]</p> <p>Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab6

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint7

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB005E8
usb1	0xFFB40000	0xFFB405E8

Offset: 0x5E8

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

hcdma7 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma7	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab7

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint8

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma8 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma8	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab8

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdmab8 Fields

Bit	Name	Description	Access	Reset
31:0	hcdmab8	These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.	RW	0x0

hcint9

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

0x3	MDATA (non-control)/SETUP (control)													
28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										
18:0	xfersize	<p>for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.</p>	RW	0x0										

hcdma9

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma9 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma9	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \cdot (nTD + 1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \cdot 5 =) 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab9

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint10

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma10 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma10	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab10

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint11

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

hcdma11 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma11	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab11

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint12

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma12 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma12	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab12

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

13:7	hubaddr	This field holds the device address of the transaction translator's hub.	RW	0x0										
6:0	prtaddr	This field is the port number of the recipient transaction translator.	RW	0x0										

hcint13

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB006A8
usb1	0xFFB40000	0xFFB406A8

hcdma13 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma13	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab13

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint14

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma14 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma14	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N]</p> <p>Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab14

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint15

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma15 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma15	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8bytes*5=)$ 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab15

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

Device Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Device mode.

Offset: 0x800

dcfg on page 19-379

This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

dctl on page 19-383

dsts on page 19-388

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

diepmsk on page 19-390

This register works with each of the Device IN Endpoint Interrupt (DIEPINT_n) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINT_n register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

doepmsk on page 19-392

This register works with each of the Device OUT Endpoint Interrupt (DOEPINT_n) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the DOEPINT_n register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

daint on page 19-394

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINT_n/DOEPINT_n).

daintmsk on page 19-400

The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

dvbusdis on page 19-405

This register specifies the VBUS discharge time after VBUS pulsing during SRP.

dvbuspulse on page 19-406

This register specifies the VBUS pulsing time during SRP.

dthrctl on page 19-407

Thresholding is not supported in Slave mode and so this register must not be programmed in Slave mode. For threshold support, the AHB must be run at 60 MHz or higher.

diepempmsk on page 19-410

This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINT_n.TxfEmp).

diepctl0 on page 19-413

This register covers Device Control IN Endpoint 0.

diepint0 on page 19-416

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers.

dieptsiz0 on page 19-421

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 on page 19-422

DMA Addressing.

dtxfsts0 on page 19-423

This register contains the free space information for the Device IN endpoint Tx FIFO.

diepdma0 on page 19-424

Endpoint 16.

diepctl1 on page 19-425

Endpoint_number: 1

diepint1 on page 19-431

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz1 on page 19-435

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma1 on page 19-436

doepint6 on page 19-715

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doeptsiz6 on page 19-719

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

daint

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the

Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

daintmsk

The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

0x1	Enable thresholding in the receive direction									

Bit	Name	Description	Access	Reset										
12:11	ahbthrratio	<p>These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>AHB threshold = MAC threshold</td> </tr> <tr> <td>0x1</td> <td>AHB threshold = MAC threshold /2</td> </tr> <tr> <td>0x2</td> <td>AHB threshold = MAC threshold /4</td> </tr> <tr> <td>0x3</td> <td>AHB threshold = MAC threshold /</td> </tr> </tbody> </table>	Value	Description	0x0	AHB threshold = MAC threshold	0x1	AHB threshold = MAC threshold /2	0x2	AHB threshold = MAC threshold /4	0x3	AHB threshold = MAC threshold /	RW	0x0
Value	Description													
0x0	AHB threshold = MAC threshold													
0x1	AHB threshold = MAC threshold /2													
0x2	AHB threshold = MAC threshold /4													
0x3	AHB threshold = MAC threshold /													
10:2	txthrlen	<p>This field specifies Transmit thresholding size in DWORDS. This also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length has to be at least eight DWORDS when the value of AHBThrRatio is 0. In case the AHBThrRatio is non zero the application needs to ensure that the AHB Threshold value does not go below the recommended eight DWORD. This field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).</p>	RW	0x8										
1	isothren	<p>When this bit is Set, the core enables thresholding for isochronous IN endpoints.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No thresholding</td> </tr> <tr> <td>0x1</td> <td>Enables thresholding</td> </tr> </tbody> </table>	Value	Description	0x0	No thresholding	0x1	Enables thresholding	RW	0x0				
Value	Description													
0x0	No thresholding													
0x1	Enables thresholding													

Bit	Name	Description	Access	Reset						
0	nonisothren	When this bit is Set, the core enables thresholding for Non Isochronous IN endpoints. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No thresholding</td> </tr> <tr> <td>0x1</td> <td>Enable thresholding</td> </tr> </tbody> </table>	Value	Description	0x0	No thresholding	0x1	Enable thresholding	RW	0x0
Value	Description									
0x0	No thresholding

0x1	32 bytes													
0x2	16 bytes													
0x3	8 bytes													

diepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00908
usb1	0xFFB40000	0xFFB40908

Offset: 0x908

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset						
0	xfercompl	<p>Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

dieptsiz0 Fields

Bit	Name	Description	Access	Reset
20:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
6:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma0

DMA Addressing.

Module Instance	Base Address	Register Address

diepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma0	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst0

This register contains the free space information for the Device IN endpoint TxFIFO.

Module Instance	Base Address	Register Address

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

dieptsiz1 Fields

Bit	Name	Description	Access	Reset								
30:29	mc	<p>for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetch for an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp)</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>1 packet</td> </tr> <tr> <td>0x2</td> <td>2 packets</td> </tr> <tr> <td>0x3</td> <td>3 packets</td> </tr> </tbody> </table>	Value	Description	0x1	1 packet	0x2	2 packets	0x3	3 packets	RW	0x0
Value	Description											
0x1	1 packet											
0x2	2 packets											
0x3	3 packets											
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0								
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma1 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma1	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst1

This register contains the free space information for the Device IN endpoint TxFIFO.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00938

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma2 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma2	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

DTXFSTS2

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0x1	Transfer Completed Interrupt									

dieptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma3	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst3

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0	xfercompl	<p>Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma4	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst4

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma5 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma5	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst5

This register contains the free space information for the Device IN endpoint TxFIFO.

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma6 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma6	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst6

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma7	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst7

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

1	epdisbld	<p>Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Endpoint Disabled Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Endpoint Disabled Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Endpoint Disabled Interrupt									

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.	RO	0x0						
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt		
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00A10
usb1	0xFFB40000	0xFFB40A10

Offset: 0xA10

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dieptsiz8 Fields

Bit	Name	Description	Access	Reset								
30:29	mc	<p>for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetch for an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp)</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>1 packet</td> </tr> <tr> <td>0x2</td> <td>2 packets</td> </tr> <tr> <td>0x3</td> <td>3 packets</td> </tr> </tbody> </table>	Value	Description	0x1	1 packet	0x2	2 packets	0x3	3 packets	RW	0x0
Value	Description											
0x1	1 packet											
0x2	2 packets											
0x3	3 packets											
28:19	pkcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0								
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma8	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst8

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00A28

0x1	Transfer Completed Interrupt									

dieptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00A30
usb1	0xFFB40000	0xFFB40A30

Offset: 0xA30

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

diepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma9	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst9

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00A48
usb1	0xFFB40000	0xFFB40A48

Offset: 0xA48

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dieptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma10 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma10	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst10

This register contains the free space information for the Device IN endpoint TxFIFO.

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00A68

0x1	Transfer Completed Interrupt									

dieptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

diepdma11 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma11	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

dieptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma12	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst12

This register contains the free space information for the Device IN endpoint TxFIFO.

diepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

dieptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

diepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

dieptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

dieptsiz15

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00B08
usb1	0xFFB40000	0xFFB40B08

Offset: 0xB08

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doeptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

Bit	Name	Description	Access	Reset
31:0	doepdma0	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset						
17	naksts	<p>When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>The core is transmitting non-NAK handshakes based on the FIFO status</td> </tr> <tr> <td>0x1</td> <td>The core is transmitting NAK handshakes on this endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	The core is transmitting non-NAK handshakes based on the FIFO status	0x1	The core is transmitting NAK handshakes on this endpoint	RO	0x0
Value	Description									
0x0	The core is transmitting non-NAK handshakes based on the FIFO status									
0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro) Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. h 1'b0'b0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

doeptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00B48

doeptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma2 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma2	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

doeptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma3	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

Doepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00B88
usb1	0xFFB40000	0xFFB40B88

0x1	Transfer Completed Interrupt									

doeptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma4	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

0x1	Transfer Completed Interrupt									

doeptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma5 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma5	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

0	xfercompl	<p>Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00BD0
usb1	0xFFB40000	0xFFB40BD0

Offset: 0xBD0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma6 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma6	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

doeptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma7	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdma7

15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C08
usb1	0xFFB40000	0xFFB40C08

Offset: 0xC08

doeptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C10
usb1	0xFFB40000	0xFFB40C10

Offset: 0xC10

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma8	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C28
usb1	0xFFB40000	0xFFB40C28

Offset: 0xC28

doeptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C30
usb1	0xFFB40000	0xFFB40C30

Offset: 0xC30

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma9	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C48
usb1	0xFFB40000	0xFFB40C48

doeptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C50

doepdma10 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma10	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab10

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers.

Module Instance	Base Address	Register Address

This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Status Phase Received for Control Write</td> </tr> <tr> <td>0x1</td> <td>Status Phase Received for Control Write</td> </tr> </tbody> </table>	Value	Description	0x0	No Status Phase Received for Control Write	0x1	Status Phase Received for Control Write	RO	0x0

0	xfercompl	<p>Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doepdma11 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma11	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C88
usb1	0xFFB40000	0xFFB40C88

0x1	Endpoint Disabled Interrupt									
0	xfercompl	<p>Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C90
usb1	0xFFB40000	0xFFB40C90

Offset: 0xC90

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma12	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab12
DMA Buffer Address.

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00CA8

This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00CB0
usb1	0xFFB40000	0xFFB40CB0

Offset: 0xCB0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma13 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma13	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab13

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTEPn and GINTSTS registers.

Module Instance	Base Address	Register Address

This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00CD0
usb1	0xFFB40000	0xFFB40CD0

Offset: 0xCD0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

doepdma14 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma14	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab14
DMA Buffer Address.

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	<p>Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00CE8

doeptsiz15

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

USB Data FIFO Address Map

These regions, available in both Host and Device modes, are a push/pop FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Module Instance	Base Address

The hard processor system (HPS) provides two serial peripheral interface (SPI) masters and two SPI slaves. The SPI masters and slaves are instances of the Synopsys DesignWare Synchronous Serial Interface (SSI) controller (DW_apb_ssi). †⁽⁶⁰⁾

Features of the SPI Controller

The SPI controller has the following features: †

- Serial master and serial slave controllers – Enable serial communication with serial-master or serial-slave peripheral devices. †
- Serial interface operation – Programmable choice of the following protocols:
 - Motorola SPI protocol
 - Texas Instruments Synchronous Serial Protocol
 - National Semiconductor Microwire
- DMA controller interface integrated with HPS DMA controller
- SPI master supports received serial data bit (RXD) sample delay
- Transmit and receive FIFO buffers are 256 words deep
- SPI master supports up to four slave selects
- Programmable master serial bit rate
- Programmable data item size of 4 to 16 bits
- Support for Multi-master mode through the FPGA logic

SPI Block Diagram and System Integration

The SPI supports data bus widths of 32 bits. †

SPI Block Diagram

Figure 20-1: SPI Block Diagram

The functional groupings of the main interfaces to the SPI block are as follows: †

- System bus interface
- DMA peripheral request interface
- Interrupt interface
- SPI interface

SPI Controller Signal Description

Signals from the two SPI masters and two SPI slaves can be routed to the FPGA or the HPS I/O pins. The following sections describe the signals available.

Interface to HPS I/O

Table 20-1: SPI Master Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	Out	Serial clock output from the SPI master
MOSI	1	Out	Transmit data line for the SPI master
MISO	1	In	Receive data line for the SPI master
SS0	1	Out	Slave Select 0 Slave select signal from SPI master
SS1	1	Out	Slave Select 1 Slave select signal from SPI master

Table 20-2: SPI Slave Interface Pins

CLK	1	In	Serial clock input to the SPI slave
MOSI	1	In	Receive data line for the SPI slave
MISO	1	Out	Transmit data line for the SPI slave
SS0	1	In	Slave select input to the SPI slave

FPGA Routing

Table 20-3: SPI Master Signals for FPGA routing:

Signal Name	Signal Width	Direction	Description
spim_txd	1	Out	Transmit data line for the SPI master
spim_rxd	1	In	Receive data line for the SPI master

Signal Name	Signal Width	Direction	Description
spim_ss_in_n	1	In	Master Contention Input
spim_ssi_oe_n	1	Out	Output enable for the SPI master
spim_ss_0_n	1	Out	Slave Select 0 Slave select signal from SPI master
spim_ss_1_n	1	Out	Slave Select 1 Allows second slave to be connected to this master
spim_ss_2_n	1	Out	Slave Select 2 Allows third slave to be connected to this master
spim_ss_3_n	1	Out	Slave Select 3 Allows fourth slave to be connected to this master

Table 20-4: SPI Slave Signals for FPGA Routing

spis_txd	1	Out	Transmit data line for the SPI slave
spis_rxd	1	In	Receive data line for the SPI slave
spis_ss_in_n	1	In	Master Contention Input
spis_ssi_oe_n	1	Out	Output enable for the SPI slave
spis_sclk_in	1	In	Serial clock input

Functional Description of the SPI Controller

Protocol Details and Standards Compliance

This section describes the functional operation of the SPI controller.

The host processor accesses data, control, and status information about the SPI controller through the system bus interface. The SPI also interfaces with the DMA Controller. †

The HPS includes two general-purpose SPI master controllers and two general-purpose SPI slave controllers.

The SPI controller can connect to any other SPI device using any of the following protocols:

- Motorola SPI Protocol †
- Texas Instruments Serial Protocol (SSP) †
- National Semiconductor Microwire Protocol †

SPI Controller Overview

In order for the SPI controller to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces: †

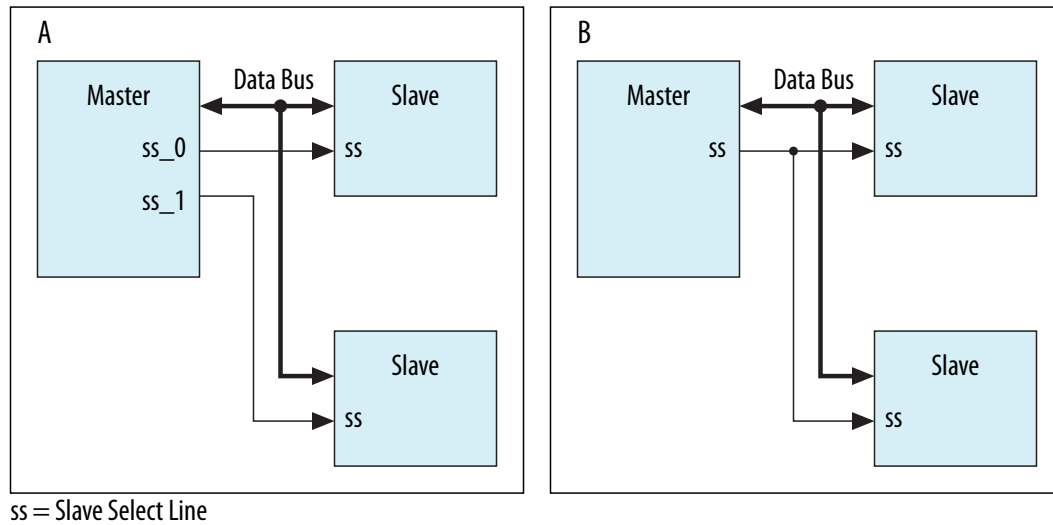

- Motorola SPI protocol – A four-wire, full-duplex serial protocol from Motorola. The slave select line is held high when the SPI controller is idle or disabled. For more information, refer to “Motorola SPI Protocol”. †
- Texas Instruments Serial Protocol (SSP) – A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol. For more information, refer to “Texas Instruments Synchronous Serial Protocol (SSP)”. †
- National Semiconductor Microwire – A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave. For more information, refer to “National Semiconductor Microwire Protocol”. You can program the FRF (frame format) bit field in the Control Register 0 (CTRLR0) to select which protocol is used. †

The serial protocols supported by the SPI controller allow for serial slaves to be selected or addressed using hardware. Serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in part A of [Figure 20-2](#). †

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. †

The main program in the software domain controls selection of the target slave device; this architecture is illustrated in part B of the [Figure 20-2](#) figure below. Software would control which slave is to respond to the serial transfer request from the master device. †

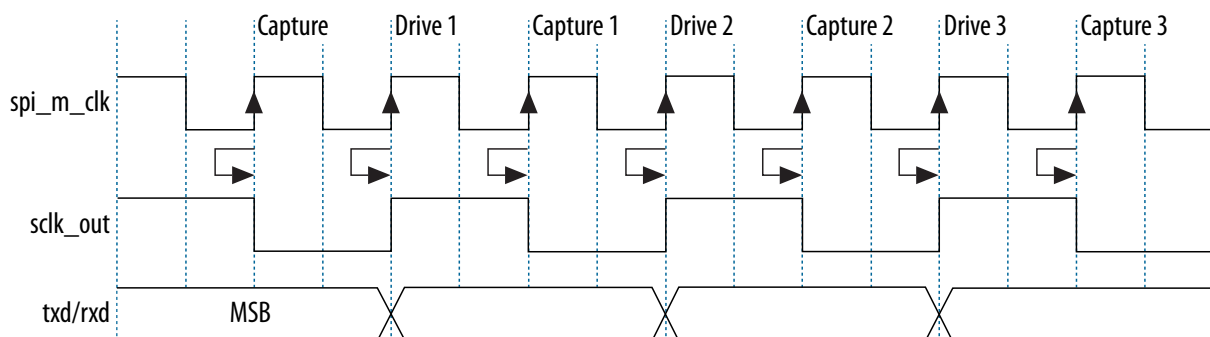

Figure 20-2: Hardware/Software Slave Selection

Serial Bit-Rate Clocks**SPI Master Bit-Rate Clock**

The maximum frequency of the SPI master bit-rate clock (`sclk_out`) is one-half the frequency of SPI master clock (`spi_m_clk`). This allows the shift control logic to capture data on one clock edge of `sclk_out` and propagate data on the opposite edge of `sclk_out` and propagate data on the opposite edge of `sclk_out`. The `sclk_out` line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates. †

Figure 20-3: Maximum `sclk_out`/`spi_m_clk` Ratio

The frequency of `sclk_out` can be derived from the equation below, where `<SPI clock>` is `spi_m_clk` for the master SPI modules and `l4_main_clk` for the slave SPI modules. †

$$F_{\text{sclk_out}} = F_{\text{<SPI clock>}} / \text{SCKDV}$$

SCKDV is a bit field in the register BAUDR, holding any even value in the range 2 to 65,534. If SCKDV is 0, then sclk_out is disabled. †

The following equation describes the frequency ratio restrictions between the bit-rate clock sclk_out and the SPI master peripheral clock. The SPI master peripheral clock must be at least double the offchip master clock. †

Table 20-5: SPI Master Peripheral Clock

SPI Master Peripheral Clock
$F_{\text{spi_m_clk}} \geq 2 \times (\text{maximum } F_{\text{sclk_out}})$ †

SPI Slave Bit-Rate Clock

The minimum frequency of l4_main_clk depends on the operation of the slave peripheral. If the slave device is *receive only*, the minimum frequency of l4_main_clk is six times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). The sclk_in signal is double synchronized to the l4_main_clk domain, and then it is edge detected; this synchronization requires three l4_main_clk periods. †

If the slave device is *transmit and receive*, the minimum frequency of l4_main_clk is eight times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). This ensures that data on the master rxd line is stable before the master shift control logic captures the data. †

The frequency ratio restrictions between the bit-rate clock sclk_in and the SPI slave peripheral clock are as follows: †

- Slave (receive only): $F_{\text{l4_main_clk}} \geq 6 \times (\text{maximum } F_{\text{sclk_in}})$ †
- Slave: $F_{\text{l4_main_clk}} \geq 8 \times (\text{maximum } F_{\text{sclk_in}})$ †

Transmit and Receive FIFO Buffers

There are two 16-bit FIFO buffers, a transmit FIFO buffer and a receive FIFO buffer, with a depth of 256. Data frames that are less than 16 bits in size must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer. †

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO buffer location; for example, you may not store two 8-bit data frames in a single FIFO buffer location. If an 8-bit data frame is required, the upper 8-bits of the FIFO buffer entry are ignored or unused when the serial shifter transmits the data. †

The transmit and receive FIFO buffers are cleared when the SPI controller is disabled (SSIENR=0) or reset.

The transmit FIFO buffer is loaded by write commands to the SPI data register (DR). Data are popped (removed) from the transmit FIFO buffer by the shift control logic into the transmit shift register. The transmit FIFO buffer generates a transmit FIFO empty interrupt request when the number of entries in the FIFO buffer is less than or equal to the FIFO buffer threshold value. The threshold value, set through the register TXFTLR, determines the level of FIFO buffer entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO buffer is nearly empty. A Transmit FIFO Overflow Interrupt is generated if you attempt to write data into an already full transmit FIFO buffer. †

Data are popped from the receive FIFO buffer by read commands to the SPI data register (DR). The receive FIFO buffer is loaded from the receive shift register by the shift control logic. The receive FIFO buffer generates a receive FIFO full interrupt request when the number of entries in the FIFO buffer is greater than or equal to the FIFO buffer threshold value plus one. The threshold value, set through register `RXFTHR`, determines the level of FIFO buffer entries at which an interrupt is generated. †

The threshold value allows you to provide early indication to the processor that the receive FIFO buffer is nearly full. A Receive FIFO Overflow Interrupt is generated when the receive shift logic attempts to load data into a completely full receive FIFO buffer. However, the newly received data are lost. A Receive FIFO Underflow Interrupt is generated if you attempt to read from an empty receive FIFO buffer. This alerts the processor that the read data are invalid. †

For more information, refer to the *Reset Manager* chapter.

SPI Interrupts

The SPI controller supports combined interrupt requests, which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking. All SPI interrupts have active-high polarity level. The SPI interrupts are described as follows: †

- Transmit FIFO Empty Interrupt – Set when the transmit FIFO buffer is equal to or below its threshold value and requires service to prevent an underrun. The threshold value, set through a software-programmable register, determines the level of transmit FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level. †
- Transmit FIFO Overflow Interrupt – Set when a master attempts to write data into the transmit FIFO buffer after it has been completely filled. When set, new data writes are discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (`TXOICR`). †
- Receive FIFO Full Interrupt – Set when the receive FIFO buffer is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level. †
- Receive FIFO Overflow Interrupt – Set when the receive logic attempts to place data into the receive FIFO buffer after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (`RXOICR`). †
- Receive FIFO Underflow Interrupt – Set when a system bus access attempts to read from the receive FIFO buffer when it is empty. When set, zeros are read back from the receive FIFO buffer. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (`RXUICR`). †
- Combined Interrupt Request – ORed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other SPI interrupt requests. †

Transmit FIFO Overflow, Transmit FIFO Empty, Receive FIFO Full, Receive FIFO Underflow, and Receive FIFO Overflow interrupts can all be masked independently, using the Interrupt Mask Register (`IMR`). †

Transfer Modes

When transferring data on the serial bus, the SPI controller operates one of several modes. The transfer mode (`TMOD`) is set by writing to the `TMOD` field in control register 0 (`CTRLR0`).

Note: The transfer mode setting does not affect the duplex of the serial transfer. `TMOD` is ignored for Microwire transfers, which are controlled by the `MWCR` register. †

Transmit and Receive

When $\text{TMOD} = 0$, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the txd line to the target device, which replies with data on the rxd line. The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. †

Transmit Only

When $\text{TMOD} = 1$, any receive data are ignored. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the txd line to the target device, which replies with data on the rxd line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO buffer. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered. †

Receive Only

When $\text{TMOD} = 2$, the transmit data are invalid. In the case of the SPI slave, the transmit FIFO buffer is never popped in Receive Only mode. The txd output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered. †

EEPROM Read

Note: This transfer mode is only valid for serial masters. †

When $\text{TMOD} = 3$, the transmit data is used to transmit an opcode, an address, or both to the EEPROM device. This takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the SPI master is transmitting data on its txd line, data on the rxd line is ignored). The SPI master continues to transmit data until the transmit FIFO buffer is empty. You should ONLY have enough data frames in the transmit FIFO buffer to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO buffer than are needed, then Read data is lost.

When the transmit FIFO buffer becomes empty (all control information has been sent), data on the receive line (rxd) is valid and is stored in the receive FIFO buffer; the txd output is held at a constant logic level. The serial transfer continues until the number of data frames received by the SPI master matches the value of the NDF field in the CTRLR1 register plus one. †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

SPI Master

The SPI master initiates and controls all serial transfers with serial-slave peripheral devices. †

The serial bit-rate clock, generated and controlled by the SPI controller, is driven out on the sclk_out line. When the SPI controller is disabled, no serial transfers can occur and sclk_out is held in “inactive” state, as defined by the serial protocol under which it operates. †

Related Information

[SPI Block Diagram](#) on page 20-2

RXD Sample Delay

The SPI master device is capable of delaying the default sample time of the `rx_d` signal in order to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the `sclk_out` signal from the master and the `rx_d` signal from the slave can mean that the timing of the `rx_d` signal, as seen by the master, has moved away from the normal sampling time.

Without the RXD sample delay, you must increase the baud rate for the transfer in order to ensure that the setup times on the `rx_d` signal are within range. This reduces the frequency of the serial interface.

Additional logic is included in the SPI master to delay the default sample time of the `rx_d` signal. This additional logic can help to increase the maximum achievable frequency on the serial bus. †

By writing to the `rsd` field of the RXD sample delay register (`rx_sample_dly`), you specify an additional amount of delay applied to the `rx_d` sample. The delay is in number of `14_main_clk` clock cycles, with 64 maximum cycles allowed (zero is reserved). If the `rsd` field is programmed with a value exceeding 64, a zero delay is applied to the `rx_d` sample.

The sample delay logic has a resolution of one `14_main_clk` cycle. Software can “train” the serial bus by coding a loop that continually reads from the slave and increments the master’s RXD sample delay value until the correct data is received by the master. †

Figure 20-4: Effects of Round Trip Routing Delays on `sclk_out` Signal

Red arrows indicates routing delay between master and slave devices
Blue arrow indicates sampling delay within slave from receiving `slk_in` to driving `txd` out

Data Transfers

The SPI master starts data transfers when all the following conditions are met:

- The SPI master is enabled
- There is at least one valid entry in the transmit FIFO buffer
- A slave device is selected

When actively transferring data, the busy flag (`BUSY`) in the status register (`SR`) is set. You must wait until the busy flag is cleared before attempting a new serial transfer. †

Note: The `BUSY` status is not set when the data are written into the transmit FIFO buffer. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO buffer, the shift logic does not begin the serial transfer until a positive edge of the `sclk_out` signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the `BUSY` status, you should first poll the Transmit FIFO Empty (`TFE`) status (waiting for 1) or wait for (`BAUDR * SPI clock`) clock cycles. †

Master SPI and SSP Serial Transfers

“Motorola SPI Protocol” and “Texas Instruments Synchronous Serial Protocol (SSP)” describe the SPI and SSP serial protocols, respectively. †

When the transfer mode is “transmit and receive” or “transmit only” (`TMOD = 0` or `TMOD = 1`, respectively), transfers are terminated by the shift control logic when the transmit FIFO buffer is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (`TXFTLR`) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor indicating that the transmit FIFO buffer is nearly empty. †

When the DMA is used in conjunction with the SPI master, the transmit data level (`DMATDLR`) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO buffer entries) into the transmit FIFO buffer before enabling a serial slave. This ensures that serial transmission does not begin until the number of data frames that make up the continuous transfer are present in the transmit FIFO buffer. †

When the transfer mode is “receive only” (`TMOD = 2`), a serial transfer is started by writing one “dummy” data word into the transmit FIFO buffer when a serial slave is selected. The `txd` output from the SPI controller is held at a constant logic level for the duration of the serial transfer. The transmit FIFO buffer is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the “number of data frames” (`NDF`) field in control register 1 (`CTRLR1`). †

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the `NDF` field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the `NDF` value plus one. This transfer mode increases the bandwidth of the system bus as the transmit FIFO buffer never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. †

When the transfer mode is “eeprom_read” (`TMOD = 3`), a serial transfer is started by writing the opcode or address, or both, into the transmit FIFO buffer when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO buffer. The end of the serial transfer is controlled by the `NDF` field in the control register 1 (`CTRLR1`).

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

The receive FIFO threshold level (`RXFRTL`) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA is used, the receive data level (`DMARDLR`) can be used to early request the DMA Controller, indicating that the receive FIFO buffer is nearly full. †

Master Microwire Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail. †

Microwire serial transfers from the SPI serial master are controlled by the Microwire Control Register (`MWCR`). The `MHS` bit field enables and disables the Microwire handshaking interface. The `MDD` bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The `MWMOD` bit field defines whether the transfer is sequential or nonsequential. †

All Microwire transfers are started by the SPI serial master when there is at least one control word in the transmit FIFO buffer and a slave is enabled. When the SPI master transmits the data frame (`MDD = 1`), the transfer is terminated by the shift logic when the transmit FIFO buffer is empty. When the SPI master receives the data frame (`MDD = 1`), the termination of the transfer depends on the setting of the `MWMOD` bit field. If the transfer is nonsequential (`MWMOD = 0`), it is terminated when the transmit FIFO buffer is empty after shifting in the data frame from the slave. When the transfer is sequential (`MWMOD = 1`), it is terminated by the shift logic when the number of data frames received is equal to the value in the `CTRLR1` register plus one. †

When the handshaking interface on the SPI master is enabled (`MHS = 1`), the status of the target slave is polled after transmission. Only when the slave reports a *ready status* does the SPI master complete the transfer and clear its `BUSY` status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a *ready status*. †

Related Information

[National Semiconductor Microwire Protocol](#) on page 20-19

SPI Slave

The SPI slave handles serial communication with transfer initiated and controlled by serial master peripheral devices.

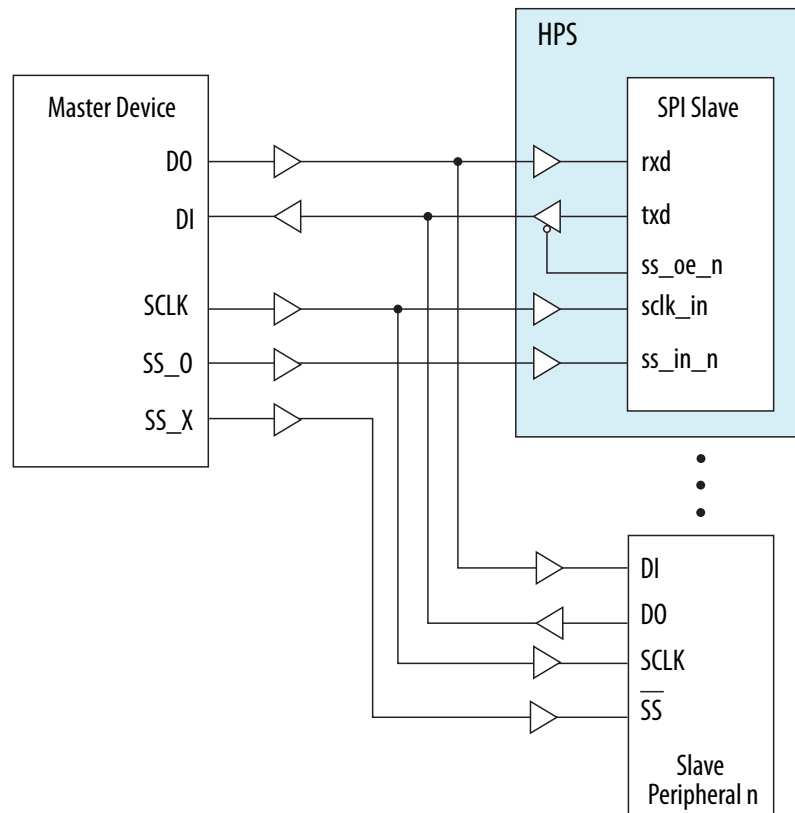

- `sclk_in`—serial clock to the SPI slave †
- `ss_in_n`—slave select input to the SPI slave †
- `ss_oe_n`—output enable for the SPI master or slave †
- `txd`—transmit data line for the SPI master or slave †
- `rx_d`—receive data line for the SPI master or slave †

When the SPI serial slave is selected, it enables its `tx_d` data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (`sclk_in`), driven from the SPI master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge. †

When the SPI serial slave is not selected, it must not interfere with data transfers between the serial-master and other serial-slave devices. When the serial slave is not selected, its `tx_d` output is buffered, resulting in a high impedance drive onto the SPI master `rx_d` line. The buffers shown in the [Figure 20-5](#) figure are external to the SPI controller. `spi_oe_n` is the SPI slave output enable signal. †

The serial clock that regulates the data transfer is generated by the serial-master device and input to the SPI slave on `sclk_in`. The slave remains in an idle state until selected by the bus master. When not actively transmitting data, the slave must hold its `txd` line in a high impedance state to avoid interference with serial transfers to other slave devices. The SPI slave output enable (`ss_oe_n`) signal is available for use to control the `txd` output buffer. The slave continues to transfer data to and from the master device as long as it is selected. If the master transmits to all serial slaves, a control bit (`SLV_OE`) in the SPI control register 0 (`CTRLR0`) can be programmed to inform the slave if it should respond with data from its `txd` line. †

Figure 20-5: SPI Slave

The `slv_oe` bit in the control register is only valid if the SPI slave interface is routed to the FPGA. To use the SPI slave in a multi master system or in a system that requires the SPI slave TXD to be tri-stated, you can do the following:

- If you want the SPI slave to control the tri-state of TXD, it must be routed to the FPGA first and use the FPGA IO. HPS I/O can also be used via the Loan I/O interface (timing permitting).
- If you do not want to route to the FPGA, then software control of the TXD (tri-state) must be performed with the already included code to control via an HPS GPIO input. Please refer to the pin connection guidelines to find which GPIO pins correspond to which HPS SPI slave SS ports.

Slave SPI and SSP Serial Transfers

“Motorola SPI Protocol” and the “Texas Instruments Synchronous Serial Protocol (SSP)” contain a description of the SPI and SSP serial protocols, respectively. †

If the SPI slave is *receive only* (`TMOD=2`), the transmit FIFO buffer need not contain valid data because the data currently in the transmit shift register is resent each time the slave device is selected. The TXE

error flag in the status register (SR) is not set when TMOD=2. You should mask the Transmit FIFO Empty Interrupt when this mode is used. †

If the SPI slave transmits data to the master, you must ensure that data exists in the transmit FIFO buffer before a transfer is initiated by the serial-master device. If the master initiates a transfer to the SPI slave when no data exists in the transmit FIFO buffer, an error flag (TXE) is set in the SPI status register, and the previously transmitted data frame is resent on t_{xd} . For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level register (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor, indicating that the transmit FIFO buffer is nearly empty. When a DMA Controller is used, the DMA transmit data level register (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. †

The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. The receive FIFO threshold level register (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA Controller is used, the DMA receive data level register (DMARDLR) can be used to early request the DMA controller, indicating that the receive FIFO buffer is nearly full. †

Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail, including timing diagrams and information about how data are structured in the transmit and receive FIFO buffers before and after a serial transfer. The Microwire protocol operates in much the same way as the SPI protocol. There is no decode of the control frame by the SPI slave device. †

Related Information

[National Semiconductor Microwire Protocol](#) on page 20-19

Glue Logic for Master Port `ss_in_n`

When configured as a master, the SPI has an input, `ssi_in_n`, which can be used by the deciding logic in a multi-master system to disable one master when another has priority. The polarity of this signal depends on the serial protocol in use, and the protocol is dynamically selectable.

Note: The signals necessary to support multi-master mode are only provided through the FPGA logic.

The table below lists the three protocols and the effect of `ss_in_n` on the ability of the master to transfer data. Note that for the SSP protocol the effect of `ss_in_n` is inverted with respect to the other protocols.

Protocol	<code>ss_in_n</code> value	Effect on Serial Transfer
Motorola SPI	1	Enabled
	0	Disabled
National Semiconductor Microwire	1	Enabled
	0	Disabled
Texas Instruments Serial Protocol (SSP)	1	Disabled
	0	Enabled

Figure 20-6: Arbitration Between Multiple Serial Masters

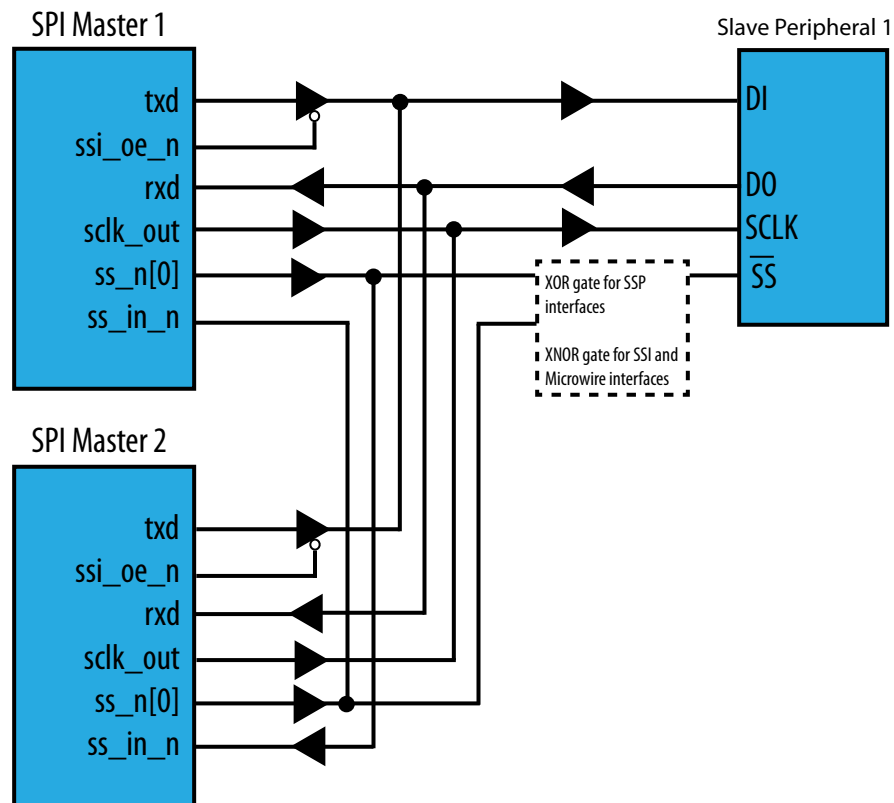

Figure 20-7: SPI Configured as Master Device

Partner Connection Interfaces

The SPI can connect to any serial-master or serial-slave peripheral device using one of several interfaces.

Motorola SPI Protocol

With SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. The data frame can be 4 to 16 bits in length. †

When the configuration parameter (SCPH = 0), data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the `txd` and `rxd` lines prior to the first serial clock edge. †

The slave select signal takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

The following signals are illustrated in the timing diagrams in this section: †

- `sclk_out`—serial clock from SPI master †
- `sclk_in`—serial clock from SPI slave †
- `ss_0_n`—slave select signal from SPI master †
- `ss_oe_n`—output enable for the SPI master or slave †
- `txd`—transmit data line for the SPI master or slave †
- `rxn`—receive data line for the SPI master or slave †

Figure 20-8: SPI Serial Format (SCPH = 0)

There are four possible transfer modes on the SPI controller for performing SPI serial transactions; refer to “Transfer Modes”. For *transmit and receive transfers* (transfer mode field (9:8) of the Control Register 0 = 0), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

Note: For *transmit only transfers* (transfer mode field (9:8) of the Control Register 0 = 1), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. As the data received from the external serial device is deemed invalid, it is not stored in the SPI receive FIFO buffer. †

For *receive only transfers* (transfer mode field (9:8) of the Control Register 0 = 2), data transmitted from the SPI controller to the external serial device is invalid, so a single dummy word is written into the transmit FIFO buffer to begin the serial transfer. The `txd` output from the SPI controller is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

For EEPROM read transfers (transfer mode field [9:8] of the Control Register 0 = 3), the opcode or the EEPROM address, or both, are written into the transmit FIFO buffer. During transmission of these control frames, received data is not captured by the SPI master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO buffer.

SPI Serial Format

Two different modes of continuous data transfers are supported:

- When clock phase $SCPH = 0$ and clock polarity $SCPOL = 0$, the SPI Controller deasserts the slave select signal between each data word and the serial clock is held to its default value while the slave select signal is deasserted.†
- When $SCPH = 1$ and $SCPOL = 1$, the slave select is held asserted (active low) for the duration of the transfer.†

Figure 20-9: Serial Format Continuous Transfers ($SCPH = 0$ and $SCPOL = 0$)

Figure 20-10: Serial Format Continuous Transfers ($SCPH = 1$ and $SCPOL = 1$)

Related Information

[Transfer Modes](#) on page 20-8

Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (ss_0_n) for one serial clock period. Data to be transmitted are driven onto the txd line one serial clock cycle later; similarly data from the slave are driven onto the rxn line. Data are propagated on the rising edge of the serial clock ($sclk_out/sclk_in$) and captured on the falling edge. The length of the data frame ranges from 4 to 16 bits.

Note: The slave select signal (ss_0_n) takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

Figure 20-11: SSP Serial Format

Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows. †

Figure 20-12: SSP Serial Format Continuous Transfer

National Semiconductor Microwire Protocol

For the master SPI, data transmission begins as soon as the output enable signal is deasserted. One-half serial clock ($sclk_out$) period later, the first bit of the control is sent out on the txd line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in $CTRLR0$. The remainder of the control word is transmitted (propagated on the falling edge of $sclk_out$) by the SPI serial master. During this transmission, no data are present (high impedance) on the serial master's rx line. †

The direction of the data word is controlled by the MDD bit field (bit 1) in the Microwire Control Register ($MWCR$). When $MDD=0$, this indicates that the SPI serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be 4 to 16 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge. †

Continuous transfers from the Microwire protocol can be sequential or nonsequential, and are controlled by the $MWMOD$ bit field (bit 0) in the $MWCR$. †

Nonsequential continuous transfers occur, with the control word for the next transfer following immediately after the LSB of the current data word. †

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer. †

During sequential continuous transfers, only one control word is transmitted from the SPI master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the SPI master terminates the transfer when the number of words received is equal to the value in the `CTRLR1` register plus one. †

When `MDD = 1`, this indicates that the SPI serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the SPI master begins transmitting the data frame to the slave peripheral. †

Note: The SPI controller does not support continuous sequential Microwire writes, where `MDD = 1` and `MWMOD = 1`. †

Continuous transfers occur with the control word for the next transfer following immediately after the LSB of the current data word.

The Microwire handshaking interface can also be enabled for SPI master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the MHS bit field (bit 2) on the `MWCR` register. When MHS is set to 1, the SPI serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers. †

After the first data word has been transmitted to the serial-slave device, the SPI master polls the `rx_d` input waiting for a ready status from the slave device. Upon reception of the ready status, the SPI master begins transmission of the next control word. After transmission of the last data frame has completed, the SPI master transmits a start bit to clear the ready status of the slave device before completing the transfer. †

In the SPI slave, data transmission begins with the falling edge of the slave select signal (`ss_in_0`). One-half serial clock (`sclk_in`) period later, the first bit of the control is present on the `rx_d` line. The length of the control word can be in the range of 1 to 16 bits and is set by writing bit field CFS in the `CTRLR0` register. The CFS bit field must be set to the size of the expected control word from the serial master. The remainder of the control word is received (captured on the rising edge of `sclk_in`) by the SPI serial slave. During this reception, no data are driven (high impedance) on the serial slave's `tx_d` line. †

The direction of the data word is controlled by the `MDD` bit field (bit 1) `MWCR` register. When `MDD=0`, this indicates that the SPI serial slave is to receive data from the external serial master. Immediately after the control word is transmitted, the serial master begins to drive the data frame onto the SPI slave `rx_d` line. Data are propagated on the falling edge of the serial clock and captured on the rising edge. The slave-select signal is held active-low during the transfer and is deasserted one-half clock cycle later after the data are transferred. The SPI slave output enable signal is held inactive for the duration of the transfer. †

When `MDD=1`, this indicates that the SPI serial slave transmits data to the external serial master. Immediately after the LSB of the control word is transmitted, the SPI slave transmits a dummy 0 bit, followed by the 4- to 16-bit data frame on the `tx_d` line. †

Continuous transfers for a SPI slave occur in the same way as those specified for the SPI master. The SPI slave does not support the handshaking interface, as there is never a busy period. †

Figure 20-13: Single SPI Serial Master Microwire Serial Transfer (MDD=0)

Figure 20-14: Single SPI Slave Microwire Serial Transfer (MDD=1)

DMA Controller Interface

The SPI controller supports DMA signaling to indicate when the receive FIFO buffer has data ready to be read or when the transmit FIFO buffer needs data. It requires two DMA channels, one for transmit data and one for receive data. The SPI controller can issue single or burst DMA transfers and accepts burst acknowledges from the DMA. System software can trigger the DMA burst mode by programming an appropriate value into the threshold registers. The typical setting of the threshold register value is half full.

To enable the DMA Controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 into the `TDMAE` bit field of DMACR register enables the SPI transmit handshaking interface. Writing a 1 into the `RDMAE` bit field of the DMACR register enables the SPI receive handshaking interface. †

Slave Interface

The host processor accesses data, control, and status information about the SPI controller through the slave interface. The SPI supports a data bus width of 32 bits.

Control and Status Register Access

Control and status registers within the SPI controller are byte-addressable. The maximum width of the control or status register in the SPI controller is 16 bits. Therefore, all read and write operations to the SPI control and status registers require only one access. †

Data Register Access

The data register (DR) within the SPI controller is 16 bits wide in order to remain consistent with the maximum serial transfer size (data frame). A write operation to DR moves data from the slave write data bus into the transmit FIFO buffer. An read operation from DR moves data from the receive FIFO buffer onto the slave readback data bus. †

Note: The DR register in the SPI controller occupies sixty-four 32-bit locations of the memory map to facilitate burst transfers. There are no burst transactions on the system bus itself, but SPI supports bursts on the system interconnect. Writing to any of these address locations has the same effect as pushing the data from the slave write data bus into the transmit FIFO buffer. Reading from any of these locations has the same effect as popping data from the receive FIFO buffer onto the slave readback data bus. The FIFO buffers on the SPI controller are not addressable.

Clocks and Resets

The SPI controller uses the clock and reset signals shown in the following table.

Table 20-6: SPI Controller Clocks and Resets

	Master	Slave
SPI clock	<code>spi_m_clk</code>	<code>l4_main_clk</code>
SPI bit-rate clock	<code>sclk_out</code>	<code>sclk_in</code>
Reset	<code>spim_rst_n</code>	<code>spis_rst_n</code>

Taking the SPI Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

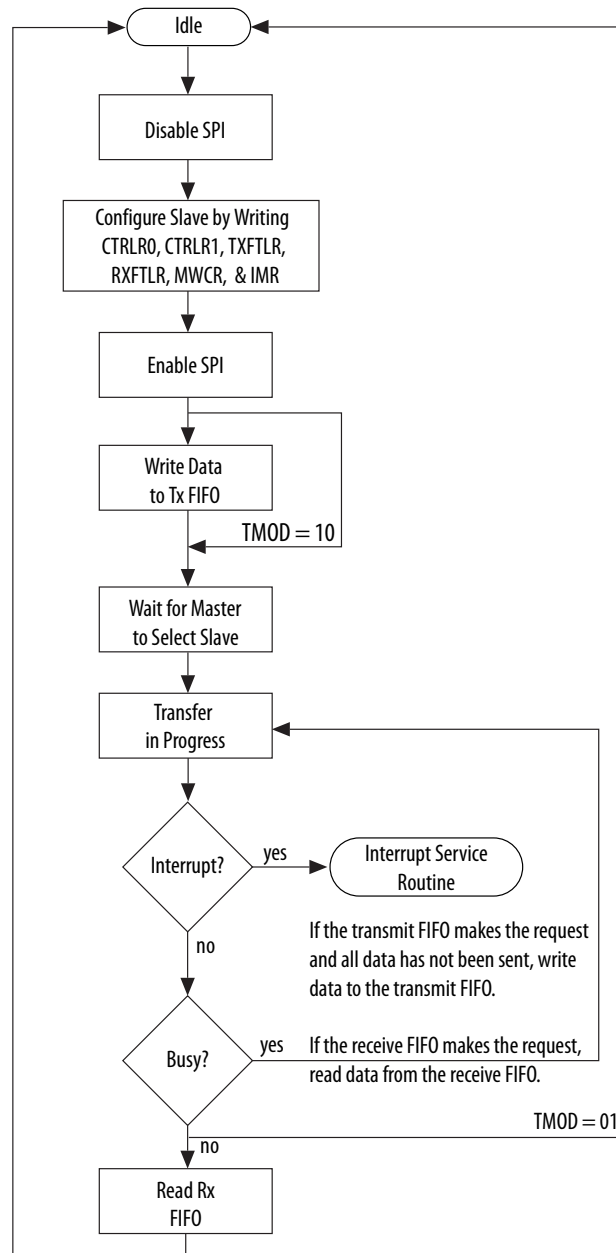

SPI Programming Model

This section describes the programming model for the SPI controller, for the following master and slave transfer types:

- Master SPI and SSP serial transfers
- Master Microwire serial transfers
- Slave SPI and SSP serial transfers
- Slave Microwire serial transfers
- Software Control for slave selection

Master SPI and SSP Serial Transfers

Figure 20-15: Master SPI or SSP Serial Transfer Software Flow

To complete an SPI or SSP serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to the SSI Enable register ($SSIENR$).
2. Set up the SPI master control registers for the transfer. You can set these registers in any order.

- Write Control Register 0 (`CTRLR0`). For SPI transfers, you must set the serial clock polarity and serial clock phase parameters identical to the target slave device.
 - If the transfer mode is receive only, write Control Register 1 (`CTRLR1`) with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
 - Write the Baud Rate Select Register (`BAUDR`) to set the baud rate for the transfer.
 - Write the Transmit and Receive FIFO Threshold Level registers (`TXFTLR` and `RXFTLR`) to set FIFO buffer threshold levels.
 - Write the `IMR` register to set up interrupt masks.
 - Write the Slave Enable Register (`SER`) register to enable the target slave for selection. If a slave is enabled at this time, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the Data Register (`DR`), the transfer does not begin until a slave is enabled.
3. Enable the SPI master by writing 1 to the `SSIENR` register.
 4. Write data for transmission to the target slave into the transmit FIFO buffer (write `DR`). If no slaves were enabled in the `SER` register at this point, enable it now to begin the transfer.
 5. Poll the `BUSY` status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).

6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is receive only ($T_{MOD} = 2$), the shift control logic stops the transfer when the specified number of frames have been received. When the transfer is done, the `BUSY` status is reset to 0.
7. If the transfer mode is not transmit only (T_{MOD} is not equal to 1), read the receive FIFO buffer until it is empty
8. Disable the SPI master by writing 0 to `SSIENR`.

Master Microwire Serial Transfers

Figure 20-16: Microwire Serial

To complete a Microwire serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to `SSIENR`.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
 - Write `CTRLR0` to set transfer parameters. If the transfer is sequential and the SPI master receives data, write `CTRLR1` with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
 - Write `BAUDR` to set the baud rate for the transfer.
 - Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
 - Write the `IMR` register to set up interrupt masks.

You can write the `SER` register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the `DR` register, the transfer does not begin until a slave is enabled.

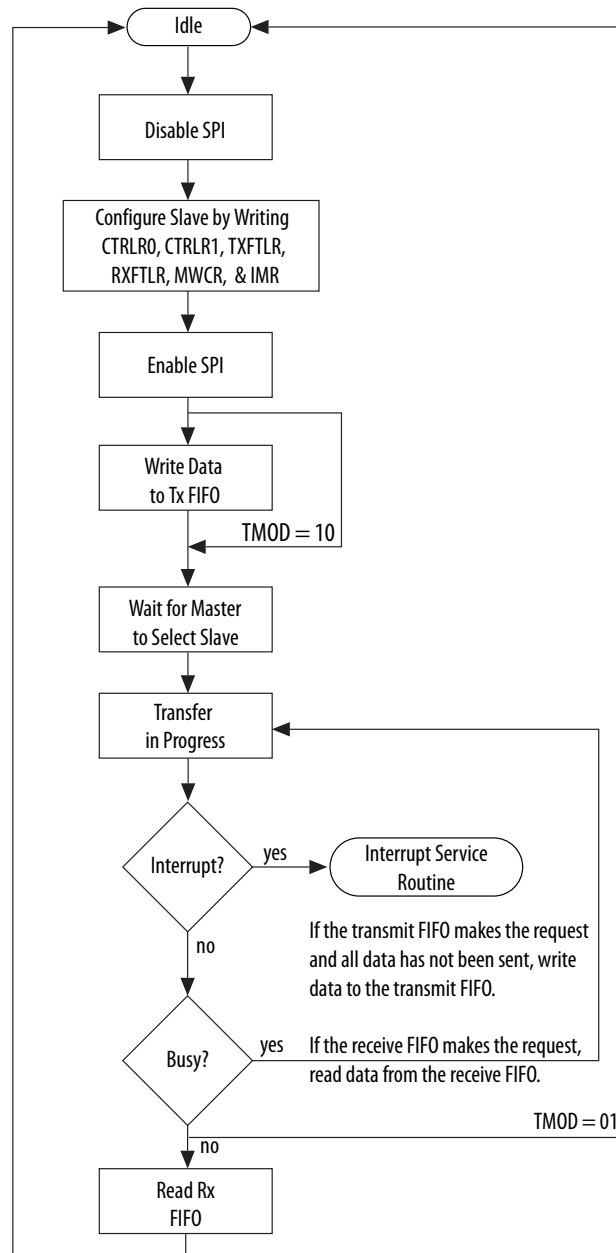

3. Enable the SPI master by writing 1 to the `SSIENR` register.
4. If the SPI master transmits data, write the control and data words into the transmit FIFO buffer (write `DR`). If the SPI master receives data, write the control word or words into the transmit FIFO buffer. If no slaves were enabled in the `SER` register at this point, enable now to begin the transfer.
5. Poll the `BUSY` status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).
6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is sequential and the SPI master receives data, the shift control logic stops the transfer when the specified number of data frames is received. When the transfer is done, the `BUSY` status is reset to 0.
7. If the SPI master receives data, read the receive FIFO buffer until it is empty.
8. Disable the SPI master by writing 0 to `SSIENR`.

Related Information

[SPI Controller Address Map and Register Definitions](#) on page 20-33

Slave SPI and SSP Serial Transfers

Figure 20-17: Slave SPI or SSP Serial Transfer Software Flow

To complete a continuous serial transfer from a serial master to the SPI slave, follow these steps:

1. If the SPI slave is enabled, disable it by writing 0 to `SSIENR`.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.

- Write `CTRLR0` (for SPI transfers, set `SCPH` and `SCPOL` identical to the master device).
 - Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
 - Write the `IMR` register to set up interrupt masks.
3. Enable the SPI slave by writing 1 to the `SSIENR` register.
 4. If the transfer mode is transmit and receive (`TMOD= 0`) or transmit only (`TMOD= 1`), write data for transmission to the master into the transmit FIFO buffer (write `DR`). If the transfer mode is receive only (`TMOD= 2`), you need not write data into the transmit FIFO buffer. The current value in the transmit shift register is retransmitted.
 5. The SPI slave is now ready for the serial transfer. The transfer begins when a serial-master device selects the SPI slave.
 6. When the transfer is underway, the `BUSY` status can be polled to return the transfer status. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).
 7. The transfer ends when the serial master removes the select input to the SPI slave. When the transfer is completed, the `BUSY` status is reset to 0.
 8. If the transfer mode is not transmit only (`TMOD != 1`), read the receive FIFO buffer until empty.
 9. Disable the SPI slave by writing 0 to `SSIENR`.

Slave Microwire Serial Transfers

For the SPI slave, the Microwire protocol operates in much the same way as the SPI protocol. The SPI slave does not decode the control frame.

Software Control for Slave Selection

When using software to select slave devices, the input select lines from serial slave devices is connected to a single slave select output on the SPI master.

Example: Slave Selection Software Flow for SPI Master

1. If the SPI master is enabled, disable it by writing 0 to `SSIENR`.
2. Write `CTRLR0` to match the required transfer.
3. If the transfer is receive only, write the number of frames into `CTRLR1`.
4. Write `BAUDR` to set the transfer baud rate.
5. Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
6. Write `IMR` register to set interrupt masks.
7. Write `SER` register bit 0 to 1 to select slave 1 in this example.
8. Write `SSIENR` register bit 0 to 1 to enable SPI master.

Example: Slave Selection Software Flow for SPI Slave

1. If the SPI slave is enabled, disable it by writing 0 to `SSIENR`.
2. Write `CTRLR0` to match the required transfer.
3. Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
4. Write `IMR` register to set interrupt masks.
5. Write `SSIENR` register bit 0 to 1 to enable SPI slave.
6. If the SPI slave transmits data, write data into TX FIFO buffer.

Note: All other SPI slaves are disabled (`SSIENR = 0`) and therefore will not respond to an active level on their `ss_in_n` port.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the SPI controller is 256 entries.

DMA Controller Operation

To enable the DMA controller interface on the SPI controller, you must write the DMA Control Register (`DMACR`). Writing a 1 to the `TDMAE` bit field of `DMACR` register enables the SPI controller transmit handshaking interface. Writing a 1 to the `RDMAE` bit field of the `DMACR` register enables the SPI controller receive handshaking. †

Related Information

[DMA Controller](#) on page 17-1

For details about the DMA controller, refer to the *DMA Controller* chapter.

Transmit FIFO Buffer Underflow

During SPI serial transfers, transmit FIFO buffer requests are made to the DMA Controller whenever the number of entries in the transmit FIFO buffer is less or equal to the value in DMA Transmit Data Level Register (`DMATDLR`); also known as the watermark level. The DMA Controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO buffer to perform serial transfers continuously, that is, when the FIFO buffer begins to empty, another DMA request should be triggered. Otherwise, the FIFO buffer will run out of data (underflow). To prevent this condition, you must set the watermark level correctly. †

Related Information

[DMA Controller](#) on page 17-1

For details about the DMA burst length microcode setup, refer to the *DMA Controller* chapter.

Transmit FIFO Watermark

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the SPI transmits data to the rate at which the DMA can respond to destination burst requests. †

Example 1: Transmit FIFO Watermark Level = 64

Consider the example where the assumption is made: †

DMA burst length = `FIFO_DEPTH - DMATDLR`

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer.

Consider the following:

- Transmit FIFO watermark level = `DMATDLR` = 64 †
- DMA burst length = `FIFO_DEPTH - DMATDLR` = 192 †
- SPI transmit `FIFO_DEPTH` = 256 †
- Block transaction size = 960 †

Figure 20-18: Transmit FIFO Watermark Level = 64

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 960/192 = 5$$

The number of burst transactions in the DMA block transfer is 5. But the watermark level, $DMATDLR$, is quite low. Therefore, there is a high probability that the SPI serial transmit line will need to transmit data when there is no data left in the transmit FIFO buffer. This is a transmit underflow condition. This occurs because the DMA has not had time to service the DMA request before the FIFO buffer becomes empty.

Example 2: Transmit FIFO Watermark Level = 192

Consider the example where the assumption is made: †

$$\text{DMA burst length} = FIFO_DEPTH - DMATDLR$$

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer. Consider the following:

- Transmit FIFO watermark level = $DMATDLR = 192$ †
- DMA burst length = $FIFO_DEPTH - DMATDLR = 64$ †
- SPI transmit $FIFO_DEPTH = 256$ †
- Block transaction size = 960 †

Figure 20-19: Transmit FIFO Watermark Level = 192

Number of burst transactions in block: †

Block transaction size/DMA burst length = $960/64 = 15$ †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, $DMATDLR$, is high. Therefore, the probability of SPI transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the SPI transmit FIFO buffer becomes empty. †

This case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case.

Transmit FIFO Buffer Overflow

Setting the DMA transaction burst length to a value greater than the watermark level that triggers the DMA request may cause overflow when there is not enough space in the transmit FIFO buffer to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

$$\text{DMA burst length} \leq \text{FIFO_DEPTH} - \text{DMATDLR}$$

In Example 2: Transmit Watermark Level = 192, the amount of space in the transmit FIFO buffer at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO buffer may be full, but not overflowed, at the completion of the burst transaction.

Therefore, for optimal operation, DMA burst length should be set at the FIFO buffer level that triggers a transmit DMA request; that is: †

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{DMATDLR}$$

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO buffer will not be full at the end of a DMA burst transfer if the SPI controller has successfully transmitted one data item or more on the serial transmit line during the transfer. †

Related Information

[Transmit FIFO Watermark](#) on page 20-30

Receive FIFO Buffer Overflow

During SPI serial transfers, receive FIFO buffer requests are made to the DMA whenever the number of entries in the receive FIFO buffer is at or above the DMA Receive Data Level Register, that is $DMARDLR + 1$. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO buffer. †

Data should be fetched by the DMA often enough for the receive FIFO buffer to accept serial transfers continuously, that is, when the FIFO buffer begins to fill, another DMA transfer is requested. Otherwise the FIFO buffer will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Choosing Receive Watermark Level

Similar to choosing the transmit watermark level, the receive watermark level, $DMARDLR + 1$, should be set to minimize the probability of overflow. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Related Information

[Texas Instruments Synchronous Serial Protocol \(SSP\)](#) on page 20-18

Receive FIFO Buffer Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

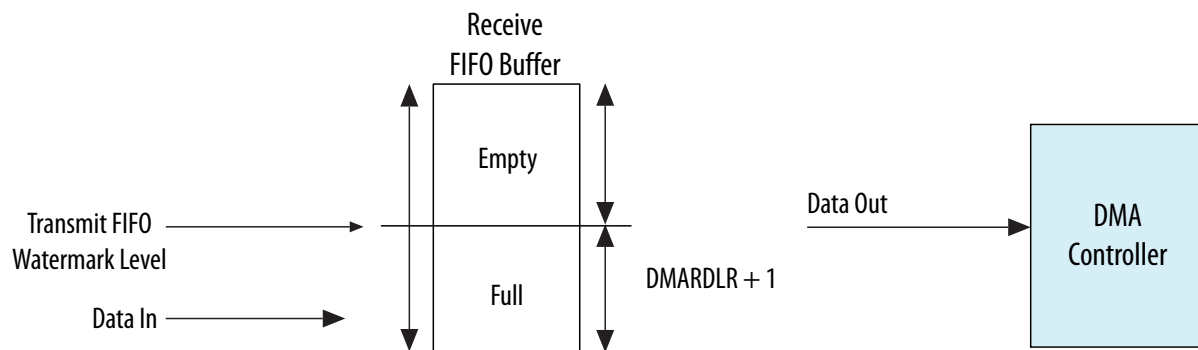

$$\text{DMA burst length} = \text{DMATDLR} + 1$$

If the number of data items in the receive FIFO buffer is equal to the source burst length at the time of the burst request is made, the receive FIFO buffer may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, $\text{DMATDLR} + 1$. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can improve bus utilization. †

Note: The receive FIFO buffer will not be empty at the end of the source burst transaction if the SPI controller has successfully received one data item or more on the serial receive line during the burst. †

Figure 20-20: Receive FIFO Buffer

SPI Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- SPI Slave Module 0
- SPI Slave Module 1
- SPI Master Module 0
- SPI Master Module 1

Related Information

ser Fields

Bit	Name	Description	Access	Reset						
3:0	ser	Each bit in this register corresponds to a slave select line (spim_ss_x_n] from the SPI Master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set.	RW	0x0						
		<table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Slave x Not Selected</td> </tr> <tr> <td>0x1</td> <td>Slave x Selected</td> </tr> </tbody> </table>	Value	Description	0x0	Slave x Not Selected	0x1	Slave x Selected		
Value	Description									
0x0	Slave x Not Selected									
0x1	Slave x Selected									

baudr

This register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the spi_m_clk divider value. It is impossible to write to this register when the SPI Master is enabled. The SPI Master is enabled and disabled by writing to the SPIENR register.

Module Instance	Base Address	Register Address
spim0	0xFFFF0000	0xFFFF0014
spim1	0xFFFF0100	0xFFFF0114

Offset: 0x14

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sckdv RW 0x0															

baudr Fields

Bit	Name	Description	Access	Reset
15:0	sckdv	The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (spim_sclk_out) is disabled. The frequency of the spim_sclk_out is derived from the following equation: $F_{\text{spim_sclk_out}} = F_{\text{spi_m_clk}} / \text{SCKDV}$ where SCKDV is any even value between 2 and 65534. For example: for $F_{\text{spi_m_clk}} = 3.6864\text{MHz}$ and $\text{SCKDV} = 2$ $F_{\text{spim_sclk_out}} = 3.6864/2 = 1.8432\text{MHz}$	RW	0x0

txftlr

This register controls the threshold value for the transmit FIFO memory. It is impossible to write to this register when the SPI Master is enabled. The SPI Master is enabled and disabled by writing to the SPIENR register.

dr

This register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SPI_EN = 1. FIFOs are reset when SPI_EN = 0. The data register occupies thirty-six 32-bit locations in the address map (0x60 to 0xec). These are all aliases for the same data register. This is done to support burst accesses. .

Module Instance	Base Address	Register Address
spim0	0xFFFF00000	0xFFFF00060 to 0xFFFF000EC
spim1	0xFFFF01000	0xFFFF01060 to 0xFFFF010EC

8:0	rxtf1	Contains the number of valid data entries in the receive FIFO.	RO	0x0

sr

Reports FIFO transfer status, and any transmission/reception errors that may have occurred. The status register may be read at any time. None of the bits in this register request an interrupt.

Module Instance	Base Address	Register Address
spis0	0xFFE02000	0xFFE02028
spis1	0xFFE03000	0xFFE03028

Offset: 0x28

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

31:0	spi_version_id	Contains the hex representation of the Synopsys component version. Consists of ASCII value for each number in the version.	RW	0x3332302A

dr

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SPI_EN = 1. FIFOs are reset when SPI_EN = 0. Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the Rx FIFO onto the bus.

Module Instance	Base Address	Register Address
spis0	0xFFE02000	0xFFE02060 to 0xFFE020EC
spis1	0xFFE03000	0xFFE03060 to 0xFFE030EC

The I²C controller provides support for a communication link between integrated circuits on a board. It is a simple two-wire bus which consists of a serial data line (SDA) and a serial clock (SCL) for use in applications such as temperature sensors and voltage level translators to EEPROMs, A/D and D/A converters, CODECs, and many types of microprocessors. †

The hard processor system (HPS) provides four I²C controllers to enable system software to communicate serially with I²C buses. Each I²C controller can operate in master or slave mode, and support standard mode of up to 100 Kbps or fast mode of up to 400 Kbps. These I²C controllers are instances of the Synopsys DesignWare APB I²C (DW_apb_i2c) controller.

Each I²C controller must be programmed to operate in either master or slave mode only. Operating as a master and slave simultaneously is not supported. † ⁽⁶²⁾

Features of the I²C Controller

The I²C controller has the following features:

- Maximum clock speed of up to 400 Kbps
- One of the following I²C operations:
 - A master in an I²C system and programmed only as a master †
 - A slave in an I²C system and programmed only as a slave †
- 7- or 10-bit addressing †
- Mixed read and write combined-format transactions in both 7-bit and 10-bit addressing mode †
- Bulk transmit mode †
- Transmit and receive buffers †
- Handles bit and byte waiting at all bus speeds †
- DMA handshaking interface †

I²C Controller Block Diagram and System Integration

The I²C controller consists of an internal slave interface, an I²C interface, and FIFO logic to buffer data between the two interfaces. †

The host processor accesses data, control, and status information about the I²C controller through a 32-bit slave interface.

Figure 21-1: I²C Controller Block Diagram

The I²C controller consists of the following modules and interfaces:

- Slave interface for control and status register (CSR) accesses and DMA transfers, allowing a master to access the CSRs and the DMA to read or write data directly.
- Two FIFO buffers for transmit and receive data, which hold the Rx FIFO and Tx FIFO buffer register banks and controllers, along with their status levels. †
- Shift logic for parallel-to-serial and serial-to-parallel conversion
 - Rx shift – Receives data into the design and extracts it in byte format. †
 - Tx shift – Presents data supplied by CPU for transfer on the I²C bus. †
- Control logic responsible for implementing the I²C protocol.

- DMA interface that generates handshaking signals to the DMA controller in order to automate the data transfer without CPU intervention. †
- Interrupt controller that generates raw interrupts and interrupt flags, allowing them to be set and cleared. †
- Receive filter for detecting events, such as start and stop conditions, in the bus; for example, start, stop and arbitration lost. †

I²C Controller Signal Description

All instances of the I²C controller connect to external pins through pin multiplexers. Pin multiplexing allows all instances to function simultaneously and independently. The pins must be connected to a pull-up resistors and the I²C bus capacitance cannot exceed 400 pF.

Table 21-1: I²C Controller Interface HPS I/O Pins

Pin Name	Signal Width	Direction	Description
SCL	1 bit	Bidirectional	Serial clock
SDA	1 bit	Bidirectional	Serial data

Table 21-2: HPS I²C Signals for FPGA Routing

Signal Name	Signal Width	Direction	Description
i2c<#>_scl	1 bit	Input	Incoming I ² C clock source. This is the input SCL signal
i2c<#>_out_clk	1 bit	Output	Outgoing I ² C clock enable. Output SCL signal. This signal is logically inverted and is synchronous to the HPS peripheral clock
i2c<#>_sda	1 bit	Input	Incoming I ² C data. This is the input SDA signal.
i2c<#>_out_data	1 bit	Output	Outgoing I ² C data enable. Output SDA signal. This signal is logically inverted and is synchronous to the HPS peripheral clock.

Figure 21-2: I²C Interface in FPGA Fabric

The figure above shows the typical connection on the I²C interface in FPGA fabric with `alt_iobuff`.

For both I²C clock and data, external IO pins are open drain connection. When output enables `i2c_out_data` and `i2c_out_clk` are asserted, external signal will be driven to ground.

I/O Buffer (ALTIOBUF)

For more information on configuring open drain I/O buffer to connect I²C signals to external I/O pins, please refer to Altera I/O Buffer (ALTIOBUF) Megafunction User Guide.

Functional Description of the I²C Controller

Feature Usage

The I²C controller can operate in standard mode (with data rates of up to 100 Kbps) or fast mode (with data rates less than or equal to 400 Kbps). Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kbps I²C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I²C bus system as they cannot follow the higher transfer rate and therefore unpredictable states would occur. †

You can attach any I²C controller to an I²C-bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus and there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. †

Behavior

You can control the I²C controller via software to be in either mode:

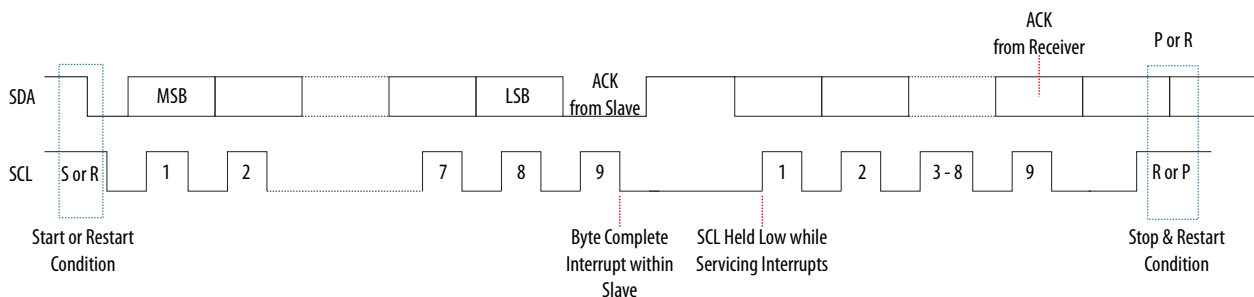

- An I²C master only, communicating with other I²C slaves.
- An I²C slave only, communicating with one or more I²C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I²C protocol also allows multiple masters to reside on the I²C bus and uses an arbitration procedure to determine bus ownership. †

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address. †

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver receives one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with an ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. †

Figure 21-3: Data Transfer on the I²C Bus †

The I²C controller is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages. †

START and STOP Generation

When operating as a master, putting data into the transmit FIFO causes the I²C controller to generate a START condition on the I²C bus. In order for the master to complete the transfer and issue a STOP condition it must find a transmit FIFO entry tagged with a stop bit. Allowing the transmit FIFO to empty without a stop bit set, the master will stall the transfer by holding the SCL line low. †

When operating as a slave, the I²C controller does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the I²C controller, it holds the SCL line low until read data has been supplied to it. This stalls the I²C bus until read data is provided to the slave I²C controller, or the I²C controller slave is disabled by writing a 0 to bit 0 of IC_ENABLE register. †

Combined Formats

The I²C controller supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. †

The I²C controller does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. †

To initiate combined format transfers, the IC_RESTART_EN bit in the IC_CON register should be set to 1. With this value set and operating as a master, when the I²C controller completes an I²C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the IC_RESTART_EN is 0, a STOP will be issued followed by a START condition. Another way to generate the RESTART condition is to set the Restart bit [10] of the DATA_CMD register. Regardless if the direction of the transfer changes or not the RESTART condition will be generated. †

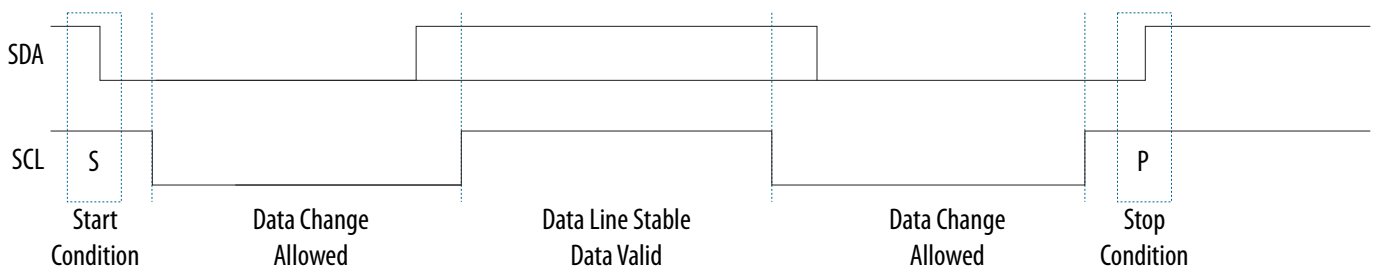

Protocol Details

START and STOP Conditions

When the bus is idle, both the SCL and SDA signals are pulled high through pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the SDA signal while SCL is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the SDA line while SCL is 1. †

The following figure shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the SDA line must be stable when SCL is 1. †

Figure 21-4: Timing Diagram for START and STOP Conditions

The signal transitions for the START or STOP condition, as shown in the figure, reflect those observed at the output signals of the master driving the I²C bus. Care should be taken when observing the SDA or SCL signals at the input signals of the slave(s), because unequal line delays may result in an incorrect SDA or SCL timing relationship. †

Addressing Slave Protocol

7-Bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in the following figure. When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave. †

Figure 21-5: 7- Bit Address Format

10-Bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. †

Figure 21-6: 10-Bit Address Format

The following table defines the special purpose and reserved first byte addresses. †

Table 21-3: I²C Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General call address. The I ² C controller places the data in the receive buffer and issues a general call interrupt.
0000 000	1	START byte. For more details, refer to “START BYTE Transfer Protocol”
0000 001	X	CBUS address. The I ² C controller ignores these accesses.
0000 010	X	Reserved
0000 011	X	Reserved
0000 1XX	X	Unused
1111 1XX	X	Reserved
1111 0XX	X	10-bit slave addressing.

Note to Table: ‘X’ indicates do not care.

[START BYTE Transfer Protocol](#) on page 21-10

Transmitting and Receiving Protocol

The master can initiate data transmission and reception to or from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to or from the bus, acting as either a slave-transmitter or slave-receiver, respectively. †

Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. †

If the master-transmitter is transmitting data as shown in the following figure, then the slave-receiver responds to the master-transmitter with an ACK pulse after every byte of data is received. †

Figure 21-7: Master-Transmitter Protocol †

Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in the following figure, then the master responds to the slave-transmitter with an ACK pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) bit so that the master can issue a STOP condition. †

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the I²C controller can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the I²C controller supports, refer to “Combined Formats” section of this chapter. †

Note: The I²C controller must be inactive on the serial port before the target slave address register, IC_TAR, can be reprogrammed. †

1. Master generates a START condition. †
2. Master transmits the START byte (0000 0001). †
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus) †
4. No slave sets the ACK signal to 0. †
5. Master generates a RESTART (R) condition. †

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated. †

Multiple Master Arbitration

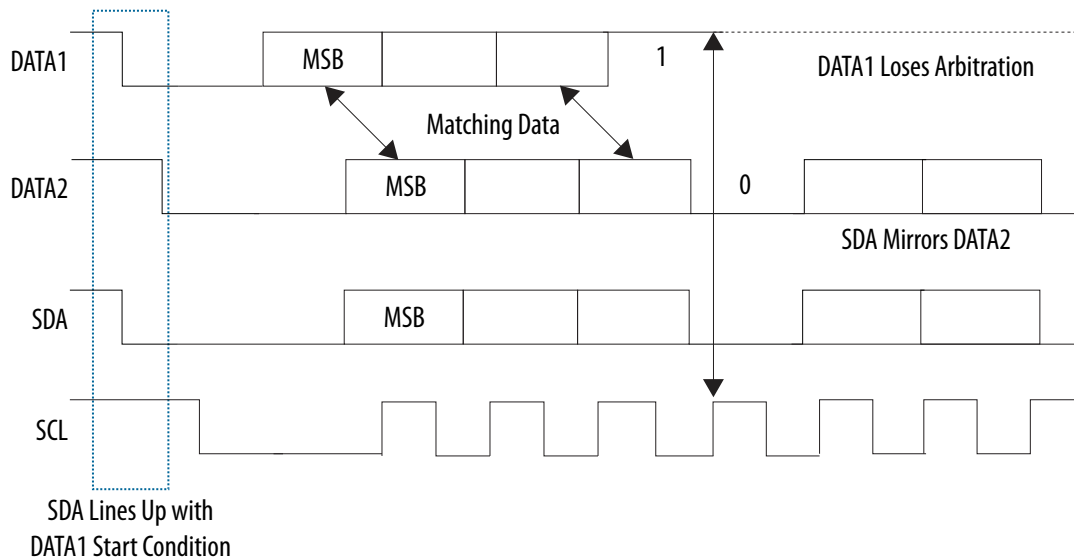

The I²C controller bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I²C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by simultaneously generating a START condition. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state. †

Arbitration takes place on the SDA line, while the SCL line is 1. The master, which transmits a 1 while the other master transmits 0, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase. †

Upon detecting that it has lost arbitration to another master, the I²C controller stops generating SCL. †

The following figure illustrates the timing of two masters arbitrating on the bus.

Figure 21-10: Multiple Master Arbitration †

The bus control is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus. †

Arbitration is not allowed between the following conditions: †

- A RESTART condition and a data bit †
- A STOP condition and a data bit †
- A RESTART condition and a STOP condition †

Slaves are not involved in the arbitration process. †

Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL clock. Clock synchronization is performed using the wired-AND connection to the SCL signal. When the master transitions the SCL clock to 0, the master starts counting the low time of the SCL clock and transitions the SCL clock signal to 1 at the beginning of the next clock period. However, if another master is holding the SCL line to 0, then the master goes into a HIGH wait state until the SCL clock line transitions to 1. †

All masters then count off their high time, and the master with the shortest high time transitions the SCL line to 0. The masters then counts out their low time and the one with the longest low time forces the other master into a HIGH wait state. Therefore, a synchronized SCL clock is generated, which is illustrated in the following figure. Optionally, slaves may hold the SCL line low to slow down the timing on the I²C bus. †

Figure 21-11: Multiple Master Clock Synchronization †

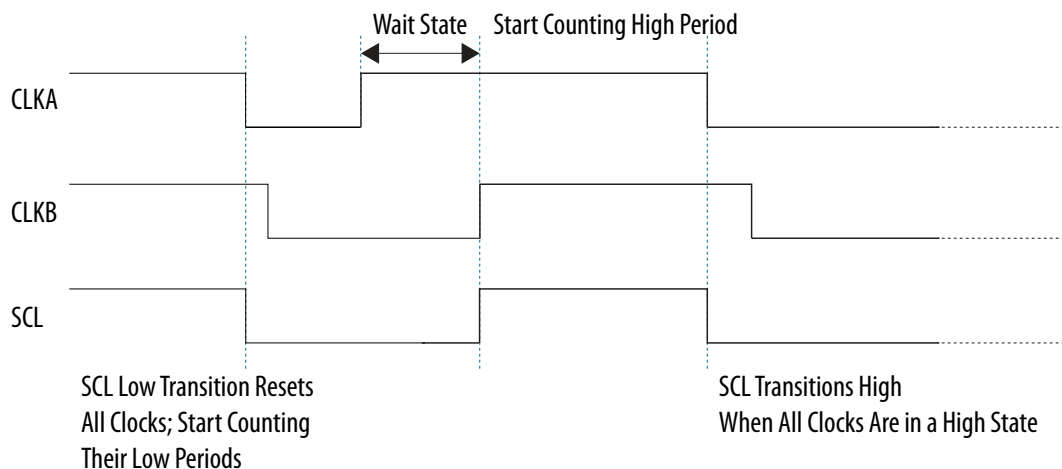

Figure 21-12: Impact of SCL Rise Time and Fall Time on Generated SCL

The following equations can be used to compute SCL high and low time:

$$SCL_High_time = [(HCNT + IC_FS_SPKLEN + 6) * ic_clk] + SCL_Fall_time$$

$$SCL_Low_time = [(LCNT + 1) * ic_clk] - SCL_Fall_time + SCL_Rise_time$$

Clock Frequency Configuration

When you configure the I²C controller as a master, the SCL count registers must be set before any I²C bus transaction can take place in order to ensure proper I/O timing. † There are four SCL count registers:

- Standard speed I²C clock SCL high count, `IC_SS_SCL_HCNT` †
- Standard speed I²C clock SCL low count, `IC_SS_SCL_LCNT` †
- Fast speed I²C clock SCL high count, `IC_FS_SCL_HCNT` †
- Fast speed I²C clock SCL low count, `IC_FS_SCL_LCNT` †

It is not necessary to program any of the SCL count registers if the I²C controller is enabled to operate only as an I²C slave, since these registers are used only to determine the SCL timing requirements for operation as an I²C master. †

Minimum High and Low Counts

When the I²C controller operates as an I²C master in both transmit and receive transfers, the minimum value that can be programmed in the SCL low count registers is 8 while the minimum value allowed for the SCL high count registers is 6. †

The minimum value of 8 for the low count registers is due to the time required for the I²C controller to drive SDA after a negative edge of SCL. The minimum value of 6 for the high count register is due to the time required for the I²C controller to sample SDA during the high period of SCL. †

The I²C controller adds one cycle to the low count register values in order to generate the low period of the SCL clock.

The I²C controller adds seven cycles to the high count register values in order to generate the high period of the SCL clock. This is due to the following factors: †

- The digital filtering applied to the SCL line incurs a delay of four `14_sp_clk` cycles. This filtering includes metastability removal and a 2-out-of-3 majority vote processing on SDA and SCL edges. †
- Whenever SCL is driven 1 to 0 by the I²C controller—that is, completing the SCL high time—an internal logic latency of three `14_sp_clk` cycles incurs. †

Consequently, the minimum SCL low time of which the I²C controller is capable is nine (9) `14_sp_clk` periods (8+1), while the minimum SCL high time is thirteen (13) `14_sp_clk` periods (6+1+3+3). †

Note: The `ic_fs_spklen` register must be set before any I²C bus transaction can take place to ensure stable operation. This register sets the duration measured in `ic_clk` cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic. †

Calculating High and Low Counts

The calculations below show an example of how to calculate SCL high and low counts for each speed mode in the I²C controller.

The equation to calculate the proper number of `14_sp_clk` clock pulses required for setting the proper SCL clocks high and low times is as follows: †

Table 21-4: Equation

$$IC_HCNT = \text{ceil}(\text{MIN_SCL_HIGHtime} * \text{OSCFREQ})$$

$$IC_LCNT = \text{ceil}(\text{MIN_SCL_LOWtime} * \text{OSCFREQ})$$

MIN_SCL_HIGHtime = minimum high period

MIN_SCL_HIGHtime =

4000 ns for 100 kbps

600 ns for 400 kbps

60 ns for 3.4 Mbs, bus loading = 100pF

160 ns for 3.4 Mbs, bus loading = 400pF

MIN_SCL_LOWtime = minimum low period

MIN_SCL_LOWtime =

4700 ns for 100 kbps

1300 ns for 400 kbps

120 ns for 3.4Mbs, bus loading = 100pF

320 ns for 3.4Mbs, bus loading = 400pF

OSCFREQ = `14_sp_clk` clock frequency (Hz)

Calculating High and Low Counts

OSCFREQ = 100 MHz

I2Cmode = fast, 400 kbps

MIN_SCL_HIGHtime = 600 ns

MIN_SCL_LOWtime = 1300 ns

```
IC_HCNT = ceil(600 ns * 100 MHz) IC_HCNTSCL_PERIOD = 60
IC_LCNT = ceil(1300 ns * 100 MHz) IC_LCNTSCL_PERIOD = 130
Actual MIN_SCL_HIGHTime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns †
```

You may configure the SCL and SDA falling time using the parameters `i2c-scl-falling-time-ns` and `i2c-sda-falling-time-ns` respectively.

SDA Hold Time

The I²C protocol specification requires 300 ns of hold time on the SDA signal in standard and fast speed modes. Board delays on the SCL and SDA signals can mean that the hold time requirement is met at the I²C master, but not at the I²C slave (or vice-versa). As each application encounters differing board delays, the I²C controller contains a software programmable register, `IC_SDA_HOLD`, to enable dynamic adjustment of the SDA hold time. `IC_SDA_HOLD` effects both slave-transmitter and master mode.

DMA Controller Interface

The I²C controller supports DMA signaling to indicate when data is ready to be read or when the transmit FIFO needs data. This support requires 2 DMA channels, one for transmit data and one for receive data. The I²C controller supports both single and burst DMA transfers. System software can choose the DMA burst mode by programming an appropriate value into the threshold registers. The recommended setting of the FIFO threshold register value is half full.

To enable the DMA controller interface on the I²C controller, you must write to the DMA control register (`DMACR`) bits. Writing a 1 into the `TDMAE` bit field of `DMACR` register enables the I²C controller transmit handshaking interface. Writing a 1 into the `RDMAE` bit field of the `DMACR` register enables the I²C controller receive handshaking interface. †

Related Information

[DMA Controller](#) on page 17-1

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Clocks

Each I²C controller is connected to the `14_sp_clk` clock, which clocks transfers in standard and fast mode. The clock input is driven by the clock manager.

Related Information

[Clock Manager](#) on page 3-1

For more information, refer to *Clock Manager* chapter.

Resets

Each I²C controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset.

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to *Reset Manager* chapter.

Taking the I²C Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

I²C Controller Programming Model

This section describes the programming model for the I²C controllers based on the two master and slave operation modes. †

Note: Each I²C controller should be set to operate only as an I²C master or as an I²C slave, never set both simultaneously. Ensure that bit 6 (`IC_SLAVE_DISABLE`) and 0 (`IC_MASTER_MODE`) of the `IC_CON` register are never set to 0 and 1, respectively. †

Slave Mode Operation

Initial Configuration

To use the I²C controller as a slave, perform the following steps: †

1. Disable the I²C controller by writing a 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the I²C controller responds. †

Note: The reset value for the I²C controller slave address is 0x55. If you are using 0x55 as the slave address, you can safely skip this step.

3. Write to the `IC_CON` register to specify which type of addressing is supported (7- or 10-bit by setting bit 3). Enable the I²C controller in slave-only mode by writing a 0 into bit 6 (`IC_SLAVE_DISABLE`) and a 0 to bit 0 (`MASTER_MODE`). †

Note: Slaves and masters do not have to be programmed with the same type of addressing 7- or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa. †

4. Enable the I²C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †

Slave-Transmitter Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and requests data, the I²C controller acts as a slave-transmitter and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the slave address in the `IC_SAR` register of the I²C controller †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter. †
3. The I²C controller asserts the `RD_REQ` interrupt (bit 5 of the `IC_RAW_INTR_STAT` register) and waits for software to respond. †

If the `RD_REQ` interrupt has been masked, due to bit 5 of the `IC_INTR_MASK` register (`M_RD_REQ` bit field) being set to 0, then it is recommended that you instruct the CPU to perform periodic reads of the `IC_RAW_INTR_STAT` register. †

- Reads that indicate bit 5 of the `IC_RAW_INTR_STAT` register (`R_RD_REQ` bit field) being set to 1 must be treated as the equivalent of the `RD_REQ` interrupt being asserted. †
- Software must then act to satisfy the I²C transfer. †
- The timing interval used should be in the order of 10 times the fastest SCL clock period the I²C controller can handle. For example, for 400 Kbps, the timing interval is 25 us. †

Note: The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I²C bus. †

4. If there is any data remaining in the TX FIFO before receiving the read request, the I²C controller asserts a `TX_ABRT` interrupt (bit 6 of the `IC_RAW_INTR_STAT` register) to flush the old data from the TX FIFO. †

Note: Because the I²C controller's TX FIFO is forced into a flushed/reset state whenever a `TX_ABRT` event occurs, it is necessary for software to release the I²C controller from this state by reading the `IC_CLR_TX_ABRT` register before attempting to write into the TX FIFO. For more information, refer to the `C_RAW_INTR_STAT` register description in the register map. †

If the `TX_ABRT` interrupt has been masked, due to of `IC_INTR_MASK[6]` register (`M_TX_ABRT` bit field) being set to 0, then it is recommended that the CPU performs periodic reads of the `IC_RAW_INTR_STAT` register. †

- Reads that indicate bit 6 (`R_TX_ABRT`) being set to 1 must be treated as the equivalent of the `TX_ABRT` interrupt being asserted. †
 - There is no further action required from software. †
 - The timing interval used should be similar to that described in the previous step for the `IC_RAW_INTR_STAT[5]` register. †
5. Software writes to the `DAT` bits of the `IC_DATA_CMD` register with the data to be written and writes a 0 in bit 8. †
 6. Software must clear the `RD_REQ` and `TX_ABRT` interrupts (bits 5 and 6, respectively) of the `IC_RAW_INTR_STAT` register before proceeding. †

If the `RD_REQ` or `TX_ABRT` interrupt is masked, then clearing of the `IC_RAW_INTR_STAT` register will have already been performed when either the `R_RD_REQ` or `R_TX_ABRT` bit has been read as 1.

7. The I²C controller transmits the byte. †
8. The master may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Receiver Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and is sending data, the I²C controller acts as a slave-receiver and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the I²C controller's slave address in the `IC_SAR` register. †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that the I²C controller is acting as a slave-receiver. †
3. I²C controller receives the transmitted byte and places it in the receive buffer. †

Note: If the RX FIFO is completely filled with data when a byte is pushed, then an overflow occurs and the I²C controller continues with subsequent I²C transfers. Because a NACK is not generated, software must recognize the overflow when indicated by the I²C controller (by the `R_RX_OVER` bit in the `IC_INTR_STAT` register) and take appropriate actions to recover from lost data. Hence, there is a real time constraint on software to service the RX FIFO before the latter overflow as there is no way to reapply pressure to the remote transmitting master. †

4. I²C controller asserts the `RX_FULL` interrupt (`IC_RAW_INTR_STAT[2]` register). †

If the `RX_FULL` interrupt has been masked, due to setting `IC_INTR_MASK[2]` register to 0 or setting `IC_TX_TL` to a value larger than 0, then it is recommended that the CPU does periodic reads of the `IC_STATUS` register. Reads of the `IC_STATUS` register, with bit 3 (`RFNE`) set at 1, must then be treated by software as the equivalent of the `RX_FULL` interrupt being asserted. †

5. Software may read the byte from the `IC_DATA_CMD` register (bits 7:0). †
6. The other master device may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Transfer Operation for Bulk Transfers

In the standard I²C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (`RD_REQ`) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. The I²C controller is designed to handle more data in the TX FIFO so that subsequent read requests can receive that data without raising an interrupt to request more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. †

This mode only occurs when I²C controller is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the I²C controller raises the read request interrupt (`RD_REQ`) and waits for data to be written into the TX FIFO before it can be sent to the remote master. †

If the `RD_REQ` interrupt is masked, due to bit 5 (`M_RD_REQ`) of the `IC_INTR_STAT` register being set to 0, then it is recommended that the CPU does periodic reads of the `IC_RAW_INTR_STAT` register. Reads of `IC_RAW_INTR_STAT` that return bit 5 (`R_RD_REQ`) set to 1 must be treated as the equivalent of the `RD_REQ` interrupt referred to in this section. †

The `RD_REQ` interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write 1 byte or more than 1 byte into the TX FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte then the slave must raise the `RD_REQ` again because the master is requesting for more data. †

If the programmer knows in advance that the remote master is requesting a packet of *n* bytes, then when another master addresses the I²C controller and requests data, the TX FIFO could be written with *n* number bytes and the remote master receives it as a continuous stream of data. For example, the I²C controller slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the TX FIFO. There is no need to issue `RD_REQ` again. †

If the remote master is to receive *n* bytes from the I²C controller but the programmer wrote a number of bytes larger than *n* to the TX FIFO, then when the slave finishes sending the requested *n* bytes, it clears the TX FIFO and ignores any excess bytes. †

The I²C controller generates a transmit abort (`TX_ABRT`) event to indicate the clearing of the TX FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO are cleared at that time. †

Master Mode Operation

Initial Configuration

For master mode operation, the target address and address format can be changed dynamically without having to disable the I²C controller. This feature is only applicable when the I²C controller is acting as a

master because the slave requires the component to be disabled before any changes can be made to the address. To use the I²C controller as a master, perform the following steps: †

For multiple I²C transfers, perform additional writes to the Tx FIFO such that the Tx FIFO does not become empty during the I²C transaction. IF the Tx FIFO is completely emptied at any stage, then the master stalls the transfer by holding the SCL line low because there was no stop bit indicating the master to issue a STOP. The master will complete the transfer when it finds a Tx FIFO entry tagged with a Stop bit.

1. Disable the I²C controller by writing 0 to bit 0 of the IC_ENABLE register. †
2. Write to the IC_CON register to set the maximum speed mode supported for slave operation (bits 2:1) and to specify whether the I²C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (bit 3). †
3. Write to the IC_TAR register the address of the I²C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I²C. The desired speed of the I²C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the IC_10BITADDR_MASTER bit field (bit 12). †
4. Enable the I²C controller by writing a 1 in bit 0 of the IC_ENABLE register. †
5. Now write the transfer direction and data to be sent to the IC_DATA_CMD register. If the IC_DATA_CMD register is written before the I²C controller is enabled, the data and commands are lost as the buffers are kept cleared when the I²C controller is not enabled. †

Dynamic IC_TAR or IC_10BITADDR_MASTER Update

The I²C controller supports dynamic updating of the IC_TAR (bits 9:0) and IC_10BITADDR_MASTER (bit 12) bit fields of the IC_TAR register. You can dynamically write to the IC_TAR register provided the following conditions are met: †

- The I²C controller is not enabled (IC_ENABLE=0); †
- The I²C controller is enabled (IC_ENABLE=1); AND I²C controller is NOT engaged in any Master (TX, RX) operation (IC_STATUS[5]=0); AND I²C controller is enabled to operate in Master mode (IC_CON[0]=1); AND there are no entries in the TX FIFO (IC_STATUS[2]=1) †

Master Transmit and Master Receive

The I²C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I²C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD). The CMD bit [8] should be written to 0 for I²C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the IC_DATA_CMD register, and a 1 should be written to the CMD bit. †

Disabling the I²C Controller

The register IC_ENABLE_STATUS is added to allow software to unambiguously determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. †

1. Define a timer interval (t_{i2c_poll}) equal to the 10 times the signaling period for the highest I²C transfer speed used in the system and supported by the I²C controller. For example, if the highest I²C transfer mode is 400 Kbps, then t_{i2c_poll} is 25 us. †
2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. †
3. Execute a blocking thread/process/function that prevents any further I²C master transactions to be started by software, but allows any pending transfers to be completed.

- This step can be ignored if the I²C controller is programmed to operate as an I²C slave only. †
- 4. The variable `POLL_COUNT` is initialized to zero. †
- 5. Set `IC_ENABLE` to 0. †
- 6. Read the `IC_ENABLE_STATUS` register and test the `IC_EN` bit (bit 0). Increment `POLL_COUNT` by one. If `POLL_COUNT >= MAX_T_POLL_COUNT`, exit with the relevant error code. †
- 7. If `IC_ENABLE_STATUS[0]` is 1, then sleep for `ti2c_poll` and proceed to the previous step. Otherwise, exit with a relevant success code. †

DMA Controller Operation

To enable the DMA controller interface on the I²C controller, you must write the DMA Control Register (`IC_DMA_CR`). Writing a 1 to the `TDMAE` bit field of `IC_DMA_CR` register enables the I²C controller transmit handshaking interface. Writing a 1 to the `RDMAE` bit field of the `IC_DMA_CR` register enables the I²C controller receive handshaking interface.†

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the I²C controller is 64 entries.

Related Information

[DMA Controller](#) on page 17-1

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit FIFO Underflow

During I²C serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the value in DMA Transmit Data Level Register (`IC_DMA_TDLR`), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of the data (underflow) causing the master to stall the transfer by holding the SCL line low. To prevent this condition, you must set the watermark level correctly.†

Related Information

[DMA Controller](#) on page 17-1

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit Watermark Level

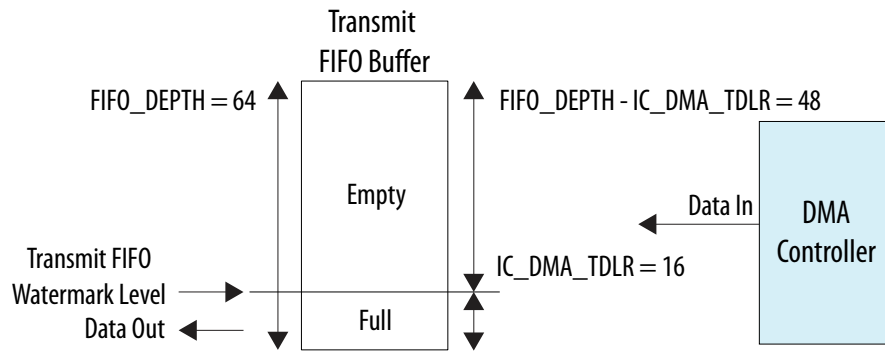

Consider the example where the assumption is made: †

DMA burst length = `FIFO_DEPTH - IC_DMA_TDLR` †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

- Case 1: `IC_DMA_TDLR = 16`: †
 - Transmit FIFO watermark level = `IC_DMA_TDLR = 16`: †
 - DMA burst length = `FIFO_DEPTH - IC_DMA_TDLR = 48`: †
 - I²C transmit `FIFO_DEPTH = 64`: †
 - Block transaction size = 240: †

Figure 21-13: Transmit FIFO Watermark Level = 16

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 240/48 = 5$$

The number of burst transactions in the DMA block transfer is 5. But the watermark level, IC_DMA_TDLR , is quite low. Therefore, the probability of transmit underflow is high where the I²C serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

- Case 2: $IC_DMA_TDLR = 48$ †
 - Transmit FIFO watermark level = $IC_DMA_TDLR = 48$ †
 - DMA burst length = $FIFO_DEPTH - IC_DMA_TDLR = 16$ †
 - I²C transmit $FIFO_DEPTH = 64$ †
 - Block transaction size = 240 †

Figure 21-14: Transmit FIFO Watermark Level = 48

Number of burst transactions in block: †

$$\text{Block transaction size/DMA burst length} = 240/16 = 15 \dagger$$

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, IC_DMA_TDLR , is high. Therefore, the probability of I²C transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the I²C transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the I²C transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

$$\text{DMA burst length} \leq \text{FIFO_DEPTH} - \text{IC_DMA_TDLR}$$

In case 2: $\text{IC_DMA_TDLR} = 48$, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{IC_DMA_TDLR}$$

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the I²C controller has successfully transmitted one data item or more on the I²C serial transmit line during the transfer. †

Receive FIFO Overflow

During I²C serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the DMA Receive Data Level Register, that is $\text{IC_DMA_RDLR} + 1$. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, $\text{IC_DMA_RDLR} + 1$, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

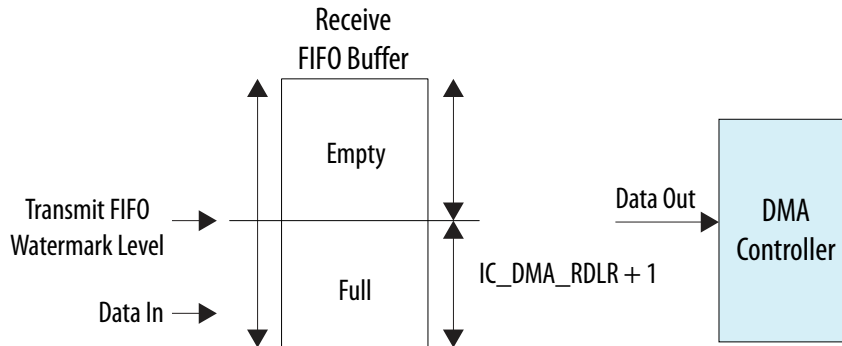

$$\text{DMA burst length} = \text{IC_DMA_RDLR} + 1$$

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, $IC_DMA_RDLR + 1$. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

Note: The receive FIFO will not be empty at the end of the source burst transaction if the I²C controller has successfully received one data item or more on the I²C serial receive line during the burst. †

0x0	General Call									
0x1	START Byte									
9:0	ic_tar	<p>This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits. If the ic_tar and ic_sar are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.</p>	RW	0x55

ic_sar Fields

Bit	Name	Description	Access	Reset
9:0	ic_sar	The Slave Address register holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only Field Bits [6:0] of the Slave Address Register are used. This register can be written only when the I2C interface is disabled, which corresponds to field bit 0 of the Enable Register being set to 0. Writes at other times have no effect. Note, the default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the Slave Address Register or Target Address Register to a reserved value.	RW	0x55

ic_data_cmd

This is the register the CPU writes to when filling the TX FIFO. Reading from this register returns bytes from RX FIFO.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset						
8	cmd	<p>This bit controls whether a read or a write is performed. This bit does not control the direction when the I2C acts as a slave. It controls only the direction when it acts as a master. When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that the CPU data is to be transmitted. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a tx_abrt interrupt (bit 6 of the Raw Intr Status Register), unless bit 11 special in the Target Address Register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a tx_abrt interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer on I2C, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing I2C. In this type of scenario, I2C ignores the Data Cmd write, generates a tx_abrt interrupt, and waits to service the RD_REQ interrupt.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Master Read</td> </tr> <tr> <td>0x0</td> <td>Master Write</td> </tr> </tbody> </table>	Value	Description	0x1	Master Read	0x0	Master Write	WO	0x0
Value	Description									
0x1	Master Read									
0x0	Master Write									
7:0	dat	<p>This Field contains the data to be transmitted or received on the I2C bus. If you are writing to these bits and want to perform a read, bits 7:0 (dat) are ignored by the I2C. However, when you read from this register, these bits return the value of data received on the I2C interface.</p>	RW	0x0						

ic_ss_scl_hcnt

				RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0	RO 0x0

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RO	0x0
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
9	r_stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
8	r_activity	This bit captures I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C - Reading the ic_clr_activity register - Reading the ic_clr_intr register - I2C reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RO	0x0
7	r_rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RO	0x0

Bit	Name	Description	Access	Reset
6	r_tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0
5	r_rd_req	This bit is set to 1 when i2c is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0
4	r_tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, this bit is set to 0.	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the Data and Command Register. When the module is disabled, this bit keeps its level until the master or slave state machines goes into idle, then interrupt is cleared.	RO	0x0
2	r_rx_full	Set when the receive buffer reaches or goes above the Receive FIFO Threshold Value(rx_tl). It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled, Bit [0] of the Enable Register set to 0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the Enable Register Bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0

Bit	Name	Description	Access	Reset
1	r_rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled, Enable Register bit[0] is set to 0 this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the Tx Rx Data and Command Register. If the module is disabled, Enable Register is set to 0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

ic_intr_mask

These bits mask their corresponding interrupt status bits.

ic_intr_mask Fields

Bit	Name	Description	Access	Reset
11	m_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RW	0x1
10	m_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RW	0x0
9	m_stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether i2c is operating in slave or master mode.	RW	0x0
8	m_activity	This bit captures i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the i2c - Reading the ic_clr_activity register - Reading the ic_clr_intr register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RW	0x0
7	m_rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RW	0x1
6	m_tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RW	0x1

Bit	Name	Description	Access	Reset
5	m_rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RW	0x1
4	m_tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	RW	0x1
3	m_tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RW	0x1
2	m_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	RW	0x1
1	m_rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RW	0x1

Bit	Name	Description	Access	Reset
0	m_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, and then this interrupt is cleared.	RW	0x1

ic_raw_intr_stat

Unlike the ic_intr_stat register, these bits are not masked so they always show the true status of the I2C.

6	tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0
5	rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The i2c holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0

Bit	Name	Description	Access	Reset
4	tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the IC_ENABLE bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0
1	rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into then, this interrupt is cleared.	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

ic_rx_tl

I2C Receive FIFO Threshold Register.

Module Instance	Base Address	Register Address

ic_rx_tl Fields

Bit	Name	Description	Access	Reset
7:0	rx_tl	Controls the level of entries (or above) that triggers the RX_FULL interrupt (bit 2 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that hardware does not allow this value to be set to a value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 1 entry, and a value of 255 sets the threshold for 256 entries.	RW	0x0

ic_tx_tl

Sets FIFO depth for Interrupt.

Bit	Name	Description	Access	Reset						
0	enable	<p>Controls whether the I2C is enabled. Software can disable I2C while it is active. However, it is important that care be taken to ensure that I2C is disabled properly. When the I2C is disabled, the following occurs: The TX FIFO and RX FIFO get flushed. Status bits in the IC_INTR_STAT register are still active until I2C goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the I2C stops the current transfer at the end of the current byte and does not acknowledge the transfer. The l4_sp_clk synchronizes pclk and ic_clk. The register ic_enable_status is added to allow software to determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. Only one register is required to be monitored. Procedure for Disabling I2C</p> <ol style="list-style-type: none"> 1. Define a timer interval (ti2c_poll) equal to the 10 times the signaling period for the highest I2C transfer speed used in the system and supported by I2C. For example, if the highest I2C transfer mode is 400 kb/s, then this ti2c_poll is 25us. 2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. 3. Execute a blocking thread/process/function that prevents any further I2C master transactions to be started by software, but allows any pending transfers to be completed. 4. The variable POLL_COUNT is initialized to zero. 5. Set IC_ENABLE to 0. 6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_T_POLL_COUNT, exit with the relevant error code. 7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disables i2c. ic_txflr

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever: - The I2C is disabled - There is a transmit abort that is, TX_ABRT bit is set in the ic_raw_intr_stat register. The slave bulk transmit mode is aborted The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Module Instance	Base Address	Register Address

ic_tx_abrt_source

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the ic_clr_tx_abrt register or the ic_clr_intr register is read. To clear Bit 9, the source of the abrt_sbyte_norstrt must be fixed first; RESTART must be enabled (ic_con[5]=1), the special bit must be cleared (ic_tar[11]), or the gc_or_start bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Module Instance	Base Address	Register Address
i2c0	0xFFFC04000	0xFFFC04080

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
31:23	tx_flush_cnt	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
16	abrt_user_abrt	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
15	abrt_slvrd_intx	When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Role of I2C: Slave-Transmitter	RW	0x0
14	abrt_slv_arblost	Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then I2C no longer own the bus. Role of I2C: Slave-Transmitter	RW	0x0
13	abrt_slvflush_txfifo	Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Role of I2C: Slave-Transmitter	RW	0x0

Bit	Name	Description	Access	Reset
12	arb_lost	Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Note: I2C can be both master and slave at the same time. Role of i2c: Master-Transmitter or Slave-Transmitter	RW	0x0
11	abrt_master_dis	User tries to initiate a Master operation with the Master mode disabled. Role of I2C: Master-Transmitter or Master-Receiver	RW	0x0
10	abrt_10b_rd_norstrt	The restart is disabled (ic_restart_en bit (ic_con[5]) =0) and the master sends a read command in 10-bit addressing mode. Role of I2C: Master-Receiver	RW	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of then abrt_sbyte_norstrt must be fixed first; restart must be enabled (ic_con[5]=1), the SPECIAL bit must be cleared (ic_tar[11]), or the GC_OR_START bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (ic_con[5]) =0) and the user is trying to send a START Byte. Role of I2C: Master	RW	0x0
8	abrt_hs_norstrt	The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
7	abrt_sbyte_ackdet	Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
6	abrt_hs_ackdet	Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
5	abrt_gcall_read	i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Role of i2c: Master-Transmitter	RW	0x0
4	abrt_gcall_noack	i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call. Role of i2c: Master-Transmitter	RW	0x0

Bit	Name	Description	Access	Reset
3	abrt_txdata_noack	This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Role of i2c: Master-Transmitter	RW	0x0
2	abrt_10addr2_noack	Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
1	abrt_10addr1_noack	Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
0	abrt_7b_addr_noack	Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0

ic_slv_data_nack_only

The register is used to generate a NACK for the data part of a transfer when i2c is acting as a slave-receiver.

Module Instance	Base Address	Register Address

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmardl	This bit field controls the level at which a DMA request is made by the receive logic. The watermark level \neq DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE = 1. For instance, when DMARDL is 0, then dma_rx_req is asserted when or more data entries are present in the receive FIFO.	RW	0x0

ic_sda_setup

This register controls the amount of time delay (in terms of number of l4_sp_clk clock periods) introduced in the rising edge of SCL relative to SDA changing by holding SCL low when I2C services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. Note: The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (l4_sp_clk)]$, so if the user requires 10 l4_sp_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the I2C when operating as a slave transmitter.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC04094
i2c1	0xFFC05000	0xFFC05094

Bit	Name	Description	Access	Reset						
0	ack_gen_call	When an ACK is asserted, (by asserting i2c_out_data) when it receives a General call. Otherwise, i2c responds with a NACK (by negating i2c_out_data).	RW	0x1						
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>I2C responds with a NACK</td> </tr> <tr> <td>0x1</td> <td>I2C responds with an ACK</td> </tr> </tbody> </table>	Value	Description	0x0	I2C responds with a NACK	0x1	I2C responds with an ACK		
Value	Description									
0x0	I2C responds with a NACK									
0x1	I2C responds with an ACK									

ic_enable_status

This register is used to report the i2c hardware status when the IC_ENABLE register is set from 1 to 0; that is, when i2c is disabled. If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE has been set to 0, bits 2:1 are only valid as soon as bit 0 is read as '0'. Note: When ic_enable has been written with '0' a delay occurs for bit 0 to be read as '0' because disabling the i2c depends on I2C bus activities.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC0409C
i2c1	0xFFC05000	0xFFC0509C
i2c2	0xFFC06000	0xFFC0609C
i2c3	0xFFC07000	0xFFC0709C

Offset: 0x9C

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													slv_rx_data_lost	slv_disab_led_while_busy	ic_en
													RO 0x0	RO 0x0	RO 0x0

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	slv_rx_data_lost	This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting of IC_ENABLE from 1 to 0. When read as 1, i2c is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and ic_enable has been set to 0, then this bit is also set to 1. When read as 0, i2c is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0
1	slv_disabled_while_busy	This bit indicates if a potential or active Slave operation has been aborted due to the setting of the ic_enable register from 1 to 0. This bit is set when the CPU writes a 0 to the ic_enable register while: (a) I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, I2C is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in i2c (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and IC_ENABLE has been set to 0, then this bit will also be set to 1. When read as 0, i2c is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0
0	ic_en	This bit always reflects the value driven on the output port ic_en. Not used in current application. When read as 1, i2c is deemed to be in an enabled state. When read as 0, i2c is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read slv_rx_data_lost (bit 2) and slv_disabled_while_busy (bit 1).	RO	0x0

ic_fs_spklen

This register is used to store the duration, measured in ic_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS or FS modes.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC040A0

ic_fs_spklen Fields

Bit	Name	Description	Access	Reset
7:0	spklen	This register must be set before any I2C bus transaction can take place to ensure stable operation. This register sets the duration, measured in ic_clk cycles, of the longest spike in the SCL or SDA lines that are filtered out by the spike suppression logic. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 2 being set.	RW	0x2

ic_comp_param_1

This is a constant read-only register that contains encoded information about the component's parameter settings.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC040F4
i2c1	0xFFC05000	0xFFC050F4
i2c2	0xFFC06000	0xFFC060F4
i2c3	0xFFC07000	0xFFC070F4

Offset: 0xF4

Access: RO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset				
7	add_encoded_params	<p>By adding in the encoded parameters, this gives firmware an easy and quick way of identifying the DesignWare component within an I/O memory map. Some critical design-time options determine how a driver should interact with the peripheral. There is a minimal area overhead by including these parameters. Allows a single driver to be developed for each component which will be self-configurable.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Add Encoded Params</td> </tr> </tbody> </table>	Value	Description	0x1	Add Encoded Params	RO	0x1
