Cyclone[®] V Hard Processor System Technical Reference Manual Revision

History.....	1-1
Introduction to the Hard Processor System.....	2-1
Features of the HPS.....	2-3
HPS Block Diagram and System Integration.....	2-4
HPS Block Diagram.....	2-4
Cortex-A9 MPCore.....	2-5
HPS Interfaces.....	2-5
System Interconnect.....	2-6
On-Chip Memory.....	2-7
Flash Memory Controllers.....	2-8
Support Peripherals.....	2-9
Interface Peripherals.....	2-11
CoreSight Debug and Trace.....	2-14
Endian Support.....	2-15
Introduction to the Hard Processor System Address Map.....	2-15
HPS Address Spaces.....	2-15
HPS Peripheral Region Address Map.....	2-17
Clock Manager.....	3-1
Features of the Clock Manager.....	3-1
Clock Manager Block Diagram and System Integration.....	3-2
L4 Peripheral Clocks.....	3-3
Functional Description of the Clock Manager.....	3-5
Clock Manager Building Blocks.....	3-5
Hardware-Managed and Software-Managed Clocks.....	3-7
Clock Groups.....	3-7
Resets.....	3-17
Safe Mode.....	3-17
Interrupts.....	3-18
Clock Usage By Module.....	3-18
Clock Manager Address Map and Register Definitions.....	3-23
Clock Manager Module Address Map.....	3-24
Reset Manager.....	4-1
Reset Manager Block Diagram and System Integration.....	4-2
HPS External Reset Sources.....	4-3
Reset Controller.....	4-4
Module Reset Signals.....	4-5

Slave Interface and Status Register.....	4-10
Functional Description of the Reset Manager.....	4-10
Reset Sequencing.....	4-11
Reset Pins.....	4-15
Reset Effects.....	4-15
Altering Warm Reset System Response.....	4-15
Reset Handshaking.....	4-16
Reset Manager Address Map and Register Definitions.....	4-16
Reset Manager Module Address Map.....	4-16
FPGA Manager.....	5-1
Features of the FPGA Manager.....	5-1
FPGA Manager Block Diagram and System Integration.....	5-2
Functional Description of the FPGA Manager.....	5-3
FPGA Manager Building Blocks.....	5-3
FPGA Configuration.....	5-4
FPGA Status.....	5-8
Error Message Extraction.....	5-8
Boot Handshake.....	5-8
General Purpose I/O.....	5-9
Clock.....	5-9
Reset.....	5-9
FPGA Manager Address Map and Register Definitions.....	5-9
FPGA Manager Module Configuration Data Address Map.....	5-9
FPGA Manager Module Address Map.....	5-10
System Manager.....	6-1
Features of the System Manager.....	6-1
System Manager Block Diagram and System Integration.....	6-2
Functional Description of the System Manager.....	6-3
Boot Configuration and System Information.....	6-3
Additional Module Control.....	6-3
Boot ROM Code.....	6-6
FPGA Interface Enables.....	6-7
ECC and Parity Control.....	6-8
Preloader Handoff Information.....	6-9
Clocks.....	6-9
Resets.....	6-9
System Manager Address Map and Register Definitions.....	6-9
System Manager Module Address Map.....	6-9
Scan Manager.....	7-1
Features of the Scan Manager.....	7-1
Scan Manager Block Diagram and System Integration.....	7-2
Arm JTAG-AP Signal Use in the Scan Manager.....	7-2
Arm JTAG-AP Scan Chains.....	7-3

Functional Description of the Scan Manager.....	7-5
Configuring HPS I/O Scan Chains.....	7-5
Communicating with the JTAG TAP Controller.....	7-6
JTAG-AP FIFO Buffer Access and Byte Command Protocol.....	7-6
Clocks.....	7-7
Resets.....	7-8
Scan Manager Address Map and Register Definitions.....	7-8
JTAG-AP Register Name Cross Reference Table.....	7-8
Scan Manager Module Registers Address Map.....	7-9
Scan Manager Revision History.....	7-16
System Interconnect.....	8-1
Features of the System Interconnect.....	8-1
System Interconnect Block Diagram and System Integration.....	8-2
Interconnect Block Diagram.....	8-2
System Interconnect Architecture.....	8-2
Main Connectivity Matrix.....	8-3
Functional Description of the Interconnect.....	8-4
Master to Slave Connectivity Matrix.....	8-4
System Interconnect Address Spaces.....	8-5
Master Caching and Buffering Overrides.....	8-13
Security.....	8-14
Configuring the Quality of Service Logic.....	8-14
Cyclic Dependency Avoidance Schemes.....	8-14
System Interconnect Master Properties.....	8-15
Interconnect Slave Properties.....	8-17
Upsizing Data Width Function.....	8-19
Downsizing Data Width Function.....	8-20
Lock Support.....	8-21
FIFO Buffers and Clock Crossing.....	8-21
System Interconnect Resets.....	8-22
System Interconnect Address Map and Register Definitions.....	8-22
L3 (NIC-301) GPV Registers Address Map.....	8-22
System Interconnect Revision History.....	8-133
HPS-FPGA Bridges.....	9-1
Features of the HPS-FPGA Bridges.....	9-1
HPS-FPGA Bridges Block Diagram and System Integration.....	9-3
Functional Description of the HPS-FPGA Bridges.....	9-4
The Global Programmers View.....	9-4
Functional Description of the FPGA-to-HPS Bridge.....	9-4
Functional Description of the HPS-to-FPGA Bridge.....	9-19
Functional Description of the Lightweight HPS-to-FPGA Bridge.....	9-34
Clocks and Resets.....	9-54
Data Width Sizing.....	9-56
HPS-FPGA Bridges Address Map and Register Definitions.....	9-56
HPS-FPGA Bridges Revision History.....	9-57

Cortex-A9 Microprocessor Unit Subsystem.....	10-1
Features of the Cortex-A9 MPU Subsystem.....	10-1
Cortex-A9 MPU Subsystem Block Diagram and System Integration.....	10-2
Cortex-A9 MPU Subsystem with System Interconnect.....	10-2
Cortex-A9 MPU Subsystem Internals.....	10-3
Cortex-A9 MPCore.....	10-4
Functional Description.....	10-4
Implementation Details.....	10-5
Cortex-A9 Processor.....	10-6
Interactive Debugging Features.....	10-7
L1 Caches.....	10-7
Preload Engine.....	10-7
Floating Point Unit.....	10-8
NEON Multimedia Processing Engine.....	10-8
Memory Management Unit.....	10-9
Performance Monitoring Unit.....	10-12
Arm Cortex-A9 MPCore Timers.....	10-12
Generic Interrupt Controller.....	10-13
Global Timer.....	10-25
Snoop Control Unit.....	10-26
Accelerator Coherency Port.....	10-27
ACP ID Mapper.....	10-32
Functional Description.....	10-32
Implementation Details.....	10-32
ACP ID Mapper Address Map and Register Definitions.....	10-37
L2 Cache.....	10-62
Functional Description.....	10-62
CPU Prefetch.....	10-69
Debugging Modules.....	10-69
Program Trace.....	10-69
Event Trace.....	10-70
Cross-Triggering.....	10-70
Clocks.....	10-71
Cortex-A9 MPU Subsystem Register Implementation.....	10-71
Cortex-A9 MPU Subsystem Address Map.....	10-72
L2 Cache Controller Address Map.....	10-73
CoreSight Debug and Trace.....	11-1
Features of CoreSight Debug and Trace.....	11-2
Arm CoreSight Documentation.....	11-2
CoreSight Debug and Trace Block Diagram and System Integration.....	11-3
Functional Description of CoreSight Debug and Trace.....	11-4
Debug Access Port.....	11-4
System Trace Macrocell.....	11-4
Trace Funnel.....	11-5
CoreSight Trace Memory Controller.....	11-5

AMBA Trace Bus Replicator.....	11-6
Trace Port Interface Unit.....	11-6
Embedded Cross Trigger System.....	11-6
Program Trace Macrocell.....	11-11
HPS Debug APB Interface.....	11-11
FPGA Interface.....	11-11
Debug Clocks.....	11-14
Debug Resets.....	11-15
CoreSight Debug and Trace Programming Model.....	11-16
Coresight Component Address.....	11-17
STM Channels.....	11-18
CTI Trigger Connections to Outside the Debug System.....	11-19
Configuring Embedded Cross-Trigger Connections.....	11-21
CoreSight Debug and Trace Address Map and Register Definitions.....	11-23
System Trace Macrocell (STM) Module Address Map.....	11-24
Debug Access Port (DAP) Module Address Map.....	11-24
MPU Address Map.....	11-26
MPU L2 Cache Controller (L2C-310) Module Address Map.....	11-27

SDRAM Controller Subsystem.....12-1

Features of the SDRAM Controller Subsystem.....	12-1
SDRAM Controller Subsystem Block Diagram.....	12-2
SDRAM Controller Memory Options.....	12-3
SDRAM Controller Subsystem Interfaces.....	12-4
MPU Subsystem Interface.....	12-4
L3 Interconnect Interface.....	12-4
CSR Interface.....	12-5
FPGA-to-HPS SDRAM Interface.....	12-5
Memory Controller Architecture.....	12-6
Multi-Port Front End.....	12-7
Single-Port Controller.....	12-8
Functional Description of the SDRAM Controller Subsystem.....	12-10
MPFE Operation Ordering.....	12-10
MPFE Multi-Port Arbitration.....	12-10
MPFE SDRAM Burst Scheduling.....	12-13
Single-Port Controller Operation.....	12-14
SDRAM Power Management.....	12-24
DDR PHY.....	12-25
DDR Calibration.....	12-25
Clocks.....	12-25
Resets.....	12-26
Taking the SDRAM Controller Subsystem Out of Reset	12-26
Port Mappings.....	12-26
Initialization.....	12-27
FPGA-to-SDRAM Protocol Details.....	12-28
SDRAM Controller Subsystem Programming Model.....	12-32
HPS Memory Interface Architecture.....	12-32
HPS Memory Interface Configuration.....	12-32

HPS Memory Interface Simulation.....	12-33
Generating a Preloader Image for HPS with EMIF.....	12-34
Debugging HPS SDRAM in the Preloader.....	12-35
Enabling UART or Semihosting Printout.....	12-35
Enabling Simple Memory Test.....	12-36
Enabling the Debug Report.....	12-37
Writing a Predefined Data Pattern to SDRAM in the Preloader.....	12-40
SDRAM Controller Address Map and Register Definitions.....	12-41
SDRAM Controller Address Map.....	12-41
On-Chip Memory.....	13-1
On-Chip RAM.....	13-1
Features of the On-Chip RAM.....	13-1
On-Chip RAM Block Diagram and System Integration.....	13-1
Functional Description of the On-Chip RAM.....	13-2
Boot ROM.....	13-3
Features of the Boot ROM.....	13-3
Boot ROM Block Diagram and System Integration.....	13-3
Functional Description of the Boot ROM.....	13-3
On-Chip Memory Address Map and Register Definitions.....	13-4
On-chip RAM Address Map.....	13-4
Boot ROM Address Map.....	13-4
NAND Flash Controller.....	14-1
NAND Flash Controller Features.....	14-1
NAND Flash Controller Block Diagram and System Integration.....	14-2
NAND Flash Controller Signal Descriptions.....	14-2
Functional Description of the NAND Flash Controller.....	14-3
Discovery and Initialization.....	14-3
Bootstrap Interface.....	14-4
Configuration by Host.....	14-5
Local Memory Buffer.....	14-6
Clocks.....	14-6
Resets.....	14-7
Indexed Addressing.....	14-7
Command Mapping.....	14-8
Data DMA.....	14-14
ECC.....	14-18
NAND Flash Controller Programming Model.....	14-21
Basic Flash Programming.....	14-22
Flash-Related Special Function Operations.....	14-25
NAND Flash Controller Address Map and Register Definitions.....	14-33
NAND Controller Module Data (AXI Slave) Address Map.....	14-33
NAND Flash Controller Module Registers (AXI Slave) Address Map.....	14-34
SD/MMC Controller.....	15-1

Features of the SD/MMC Controller.....	15-1
SD Card Support Matrix.....	15-2
MMC Support Matrix.....	15-3
SD/MMC Controller Block Diagram and System Integration.....	15-3
SD/MMC Controller Signal Description.....	15-4
Functional Description of the SD/MMC Controller.....	15-5
SD/MMC/CE-ATA Protocol.....	15-5
BIU.....	15-6
CIU.....	15-20
Clocks.....	15-35
Resets.....	15-36
Voltage Switching.....	15-37
SD/MMC Controller Programming Model.....	15-39
Software and Hardware Restrictions [†]	15-39
Initialization [†]	15-41
Controller/DMA/FIFO Buffer Reset Usage.....	15-47
Enabling ECC.....	15-47
Enabling FIFO Buffer ECC.....	15-47
Non-Data Transfer Commands.....	15-48
Data Transfer Commands.....	15-50
Transfer Stop and Abort Commands.....	15-56
Internal DMA Controller Operations.....	15-58
Commands for SDIO Card Devices.....	15-60
CE-ATA Data Transfer Commands.....	15-62
Card Read Threshold.....	15-70
Interrupt and Error Handling.....	15-73
Bootling Operation for eMMC and MMC.....	15-74
SD/MMC Controller Address Map and Register Definitions.....	15-84
SDMMC Module Address Map.....	15-84

Quad SPI Flash Controller..... 16-1

Features of the Quad SPI Flash Controller.....	16-1
Quad SPI Flash Controller Block Diagram and System Integration.....	16-2
Interface Signals.....	16-3
Functional Description of the Quad SPI Flash Controller.....	16-3
Overview.....	16-3
Data Slave Interface.....	16-4
SPI Legacy Mode.....	16-7
Register Slave Interface.....	16-8
Local Memory Buffer.....	16-8
DMA Peripheral Request Controller.....	16-9
Arbitration between Direct/Indirect Access Controller and STIG.....	16-10
Configuring the Flash Device.....	16-10
XIP Mode.....	16-12
Write Protection.....	16-12
Data Slave Sequential Access Detection.....	16-13
Clocks.....	16-13
Resets.....	16-13

Interrupts.....	16-14
Quad SPI Flash Controller Programming Model.....	16-15
Setting Up the Quad SPI Flash Controller.....	16-15
Indirect Read Operation with DMA Disabled.....	16-16
Indirect Read Operation with DMA Enabled.....	16-16
Indirect Write Operation with DMA Disabled.....	16-17
Indirect Write Operation with DMA Enabled.....	16-17
XIP Mode Operations.....	16-18
Quad SPI Flash Controller Address Map and Register Definitions.....	16-19
QSPI Flash Controller Module Registers Address Map.....	16-20
QSPI Flash Module Data (AHB Slave) Address Map.....	16-61
DMA Controller.....	17-1
Features of the DMA Controller.....	17-1
DMA Controller Block Diagram and System Integration.....	17-3
Functional Description of the DMA Controller.....	17-3
Peripheral Request Interface.....	17-4
DMA Controller Address Map and Register Definitions.....	17-7
Address Map and Register Definitions.....	17-9
Ethernet Media Access Controller.....	18-1
Features of the Ethernet MAC.....	18-2
MAC.....	18-2
DMA.....	18-2
Management Interface.....	18-3
Acceleration.....	18-3
PHY Interface.....	18-3
EMAC Block Diagram and System Integration.....	18-4
EMAC Signal Description.....	18-5
HPS EMAC I/O Signals.....	18-6
FPGA EMAC I/O Signals.....	18-8
PHY Management Interface.....	18-11
EMAC Internal Interfaces.....	18-12
DMA Master Interface.....	18-12
Timestamp Interface.....	18-13
Functional Description of the EMAC.....	18-14
Transmit and Receive Data FIFO Buffers.....	18-15
DMA Controller.....	18-16
Descriptor Overview.....	18-29
IEEE 1588-2002 Timestamps.....	18-46
IEEE 1588-2008 Advanced Timestamps.....	18-52
IEEE 802.3az Energy Efficient Ethernet.....	18-55
Checksum Offload.....	18-56
Frame Filtering.....	18-56
Clocks and Resets.....	18-61
Interrupts.....	18-63
Ethernet MAC Programming Model.....	18-63

System Level EMAC Configuration Registers.....	18-63
EMAC FPGA Interface Initialization.....	18-65
EMAC HPS Interface Initialization.....	18-66
DMA Initialization.....	18-66
EMAC Initialization and Configuration.....	18-67
Performing Normal Receive and Transmit Operation.....	18-68
Stopping and Starting Transmission.....	18-68
Programming Guidelines for Energy Efficient Ethernet.....	18-69
Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output.....	18-70
Ethernet MAC Address Map and Register Definitions.....	18-72
EMAC Module Address Map.....	18-72
USB 2.0 OTG Controller.....	19-1
Features of the USB OTG Controller.....	19-2
Supported PHYS.....	19-3
USB OTG Controller Block Diagram and System Integration.....	19-4
USB 2.0 ULPI PHY Signal Description.....	19-5
Functional Description of the USB OTG Controller.....	19-6
USB OTG Controller Block Description.....	19-6
Local Memory Buffer.....	19-10
Clocks.....	19-10
Resets.....	19-10
Interrupts.....	19-11
USB OTG Controller Programming Model.....	19-13
Enabling ECC.....	19-13
Enabling SPRAM ECCs.....	19-13
Host Operation.....	19-14
Device Operation.....	19-15
USB 2.0 OTG Controller Address Map and Register Definitions.....	19-17
USB OTG Controller Module Registers Address Map.....	19-17
SPI Controller.....	20-1
Features of the SPI Controller.....	20-1
SPI Block Diagram and System Integration.....	20-2
SPI Block Diagram.....	20-2
SPI Controller Signal Description.....	20-3
Interface to HPS I/O.....	20-3
FPGA Routing.....	20-3
Functional Description of the SPI Controller.....	20-4
Protocol Details and Standards Compliance.....	20-4
SPI Controller Overview.....	20-5
Transfer Modes.....	20-8
SPI Master.....	20-9
SPI Slave.....	20-12
Partner Connection Interfaces.....	20-16
DMA Controller Interface.....	20-21
Slave Interface.....	20-21

Clocks and Resets.....	20-22
SPI Programming Model.....	20-23
Master SPI and SSP Serial Transfers.....	20-24
Master Microwire Serial Transfers.....	20-26
Slave SPI and SSP Serial Transfers.....	20-28
Slave Microwire Serial Transfers.....	20-29
Software Control for Slave Selection.....	20-29
DMA Controller Operation.....	20-30
SPI Controller Address Map and Register Definitions.....	20-33
SPI Master Module Address Map.....	20-33
SPI Slave Module Address Map.....	20-61
I²C Controller.....	21-1
Features of the I ² C Controller.....	21-1
I ² C Controller Block Diagram and System Integration.....	21-2
I ² C Controller Signal Description.....	21-3
Functional Description of the I ² C Controller.....	21-4
Feature Usage.....	21-4
Behavior.....	21-5
Protocol Details.....	21-6
Multiple Master Arbitration.....	21-11
Clock Frequency Configuration.....	21-13
SDA Hold Time.....	21-15
DMA Controller Interface.....	21-15
Clocks.....	21-15
Resets.....	21-15
I ² C Controller Programming Model.....	21-16
Slave Mode Operation.....	21-16
Master Mode Operation.....	21-18
Disabling the I ² C Controller.....	21-19
DMA Controller Operation.....	21-20
I ² C Controller Address Map and Register Definitions.....	21-23
I ² C Module Address Map.....	21-23
UART Controller.....	22-1
UART Controller Features.....	22-1
UART Controller Block Diagram and System Integration.....	22-2
UART Controller Signal Description.....	22-3
HPS I/O Pins.....	22-3
FPGA Routing.....	22-3
Functional Description of the UART Controller.....	22-4
FIFO Buffer Support.....	22-4
UART(RS232) Serial Protocol.....	22-5
Automatic Flow Control.....	22-5
Clocks.....	22-7
Resets.....	22-7
Interrupts.....	22-7

DMA Controller Operation.....	22-10
Transmit FIFO Underflow.....	22-11
Transmit Watermark Level.....	22-11
Transmit FIFO Overflow.....	22-12
Receive FIFO Overflow.....	22-13
Receive Watermark Level.....	22-13
Receive FIFO Underflow.....	22-13
UART Controller Address Map and Register Definitions.....	22-14
UART Module Address Map.....	22-14
General-Purpose I/O Interface.....	23-1
Features of the GPIO Interface.....	23-1
GPIO Interface Block Diagram and System Integration.....	23-2
Functional Description of the GPIO Interface.....	23-2
Debounce Operation.....	23-2
Pin Directions.....	23-3
Taking the GPIO Interface Out of Reset	23-3
GPIO Pin State During Reset.....	23-3
GPIO Interface Programming Model.....	23-4
General-Purpose I/O Interface Address Map and Register Definitions.....	23-4
GPIO Module Address Map.....	23-4
Timer	24-1
Features of the Timer.....	24-1
Timer Block Diagram and System Integration.....	24-1
Functional Description of the Timer.....	24-2
Clocks.....	24-3
Resets.....	24-3
Interrupts.....	24-3
FPGA Interface.....	24-3
Timer Programming Model.....	24-5
Initialization.....	24-5
Enabling the Timer.....	24-5
Disabling the Timer.....	24-5
Loading the Timer Countdown Value.....	24-5
Servicing Interrupts.....	24-6
Timer Address Map and Register Definitions.....	24-6
Timer Module Address Map.....	24-6
Watchdog Timer.....	25-1
Features of the Watchdog Timer.....	25-1
Watchdog Timer Block Diagram and System Integration.....	25-2
Functional Description of the Watchdog Timer.....	25-2
Watchdog Timer Counter.....	25-2
Watchdog Timer Pause Mode.....	25-3
Watchdog Timer Clocks.....	25-3

- Watchdog Timer Resets.....25-3
- FPGA Interface.....25-4
- Watchdog Timer Programming Model.....25-4
 - Setting the Timeout Period Values..... 25-4
 - Selecting the Output Response Mode..... 25-4
 - Enabling and Initially Starting a Watchdog Timer.....25-5
 - Reloading a Watchdog Counter..... 25-5
 - Pausing a Watchdog Timer.....25-5
 - Disabling and Stopping a Watchdog Timer.....25-5
 - Watchdog Timer State Machine.....25-5
- Watchdog Timer Address Map and Register Definitions.....25-7
 - L4 Watchdog Module Address Map..... 25-7

CAN Controller..... 26-1

- Features of the CAN Controller..... 26-1
- CAN Controller Block Diagram and System Integration.....26-2
- Functional Description of the CAN Controller..... 26-3
 - Message Object..... 26-3
 - Message Interface Registers..... 26-7
 - DMA Mode..... 26-8
 - Automatic Retransmission.....26-8
 - Test Mode..... 26-8
 - L4 Slave Interface..... 26-10
 - Clocks..... 26-10
 - Software Reset.....26-10
 - Hardware Reset..... 26-11
 - Interrupts..... 26-11
- CAN Controller Programming Model.....26-12
 - Software Initialization..... 26-12
 - CAN Message Transfer.....26-13
 - Message Object Reconfiguration for Frame Reception..... 26-13
 - Message Object Reconfiguration for Frame Transmission..... 26-14
- CAN Controller Address Map and Register Definitions.....26-14
 - CAN Controller Module Address Map.....26-15
- CAN Controller Revision History..... 26-233

Introduction to the HPS Component..... 27-1

- MPU Subsystem..... 27-2
- Arm CoreSight Debug Components..... 27-2
- Interconnect..... 27-2
- HPS-to-FPGA Interfaces.....27-2
- Memory Controllers..... 27-3
- Support Peripherals.....27-3
- Interface Peripherals..... 27-3
- On-Chip Memories.....27-4

Instantiating the HPS Component.....	28-1
FPGA Interfaces.....	28-1
General Interfaces.....	28-2
FPGA-to-HPS SDRAM Interface.....	28-3
DMA Peripheral Request.....	28-5
Interrupts.....	28-5
AXI Bridges.....	28-7
Configuring HPS Clocks and Resets.....	28-8
User Clocks.....	28-8
Reset Interfaces.....	28-9
PLL Reference Clocks.....	28-10
Peripheral FPGA Clocks.....	28-11
Configuring Peripheral Pin Multiplexing.....	28-11
Configuring Peripherals.....	28-12
Connecting Unassigned Pins to GPIO.....	28-12
Using Unassigned IO as LoanIO.....	28-13
Resolving Pin Multiplexing Conflicts.....	28-13
Peripheral Signals Routed to FPGA	28-14
Configuring the External Memory Interface.....	28-14
Selecting PLL Output Frequency and Phase.....	28-15
Using the Address Span Extender Component.....	28-15
Generating and Compiling the HPS Component.....	28-16
HPS Component Interfaces.....	29-1
Memory-Mapped Interfaces.....	29-1
FPGA-to-HPS Bridge.....	29-1
HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges.....	29-2
FPGA-to-HPS SDRAM Interface.....	29-3
Clocks.....	29-4
Alternative Clock Inputs to HPS PLLs.....	29-4
User Clocks.....	29-4
AXI Bridge FPGA Interface Clocks.....	29-5
SDRAM Clocks.....	29-5
Peripheral FPGA Clocks.....	29-5
Resets.....	29-6
HPS-to-FPGA Reset Interfaces.....	29-6
HPS External Reset Request.....	29-6
Peripheral Reset Interfaces.....	29-7
Debug and Trace Interfaces.....	29-7
Trace Port Interface Unit.....	29-7
FPGA System Trace Macrocell Events Interface.....	29-7
FPGA Cross Trigger Interface.....	29-7
Debug APB Interface.....	29-7
Peripheral Signal Interfaces.....	29-7
DMA Controller Interface.....	29-7
Other Interfaces.....	29-8

MPU Standby and Event Interfaces..... 29-8
 General Purpose Signals..... 29-9
 FPGA-to-HPS Interrupts..... 29-9
 Boot from FPGA Interface..... 29-9
 Input-only General Purpose Interface..... 29-9

Simulating the HPS Component..... 30-1

Simulation Flows..... 30-2
 Setting Up the HPS Component for Simulation..... 30-3
 Generating the HPS Simulation Model in Platform Designer (Standard)..... 30-5
 Running the Simulations..... 30-5
 Clock and Reset Interfaces..... 30-9
 Clock Interface..... 30-9
 Reset Interface..... 30-10
 FPGA-to-HPS AXI Slave Interface..... 30-11
 HPS-to-FPGA AXI Master Interface..... 30-12
 Lightweight HPS-to-FPGA AXI Master Interface..... 30-12
 FPGA-to-HPS SDRAM Interface..... 30-13
 HPS Memory Interface Simulation..... 30-13
 HPS-to-FPGA MPU Event Interface..... 30-14
 Interrupts Interface..... 30-14
 HPS-to-FPGA Debug APB Interface..... 30-16
 FPGA-to-HPS System Trace Macrocell Hardware Event Interface..... 30-16
 HPS-to-FPGA Cross-Trigger Interface..... 30-17
 HPS-to-FPGA Trace Port Interface..... 30-17
 FPGA-to-HPS DMA Handshake Interface..... 30-18
 Boot from FPGA Interface..... 30-19
 General Purpose Input Interface..... 30-20

Booting and Configuration..... A-1

Boot Overview..... A-1
 FPGA Configuration Overview..... A-1
 Booting and Configuration Options..... A-2
 Boot Definitions..... A-5
 Reset..... A-5
 Boot ROM..... A-5
 Boot Select..... A-6
 Flash Memory Devices for Booting..... A-13
 Clock Select..... A-25
 I/O Configuration..... A-25
 L4 Watchdog 0 Timer..... A-26
 Preloader..... A-26
 U-Boot Loader..... A-26
 Boot ROM Flow..... A-26
 Typical Preloader Boot Flow..... A-28

Chapter	Date of Last Update
General-Purpose I/O Interface	June 14, 2019
Timer	June 30, 2014
Watchdog Timer	November 2, 2015
CAN Controller	November 2, 2015
Introduction to the HPS Component	December 30, 2013
Instantiating the HPS Component	November 2, 2015
HPS Component Interfaces	May 4, 2015
Simulating the HPS Component	May 3, 2016
Bootting and Configuration	July 17, 2018

Table 1-2: Introduction to the Hard Processor Revision History

Document Version	Changes
2016.10.28	<ul style="list-style-type: none"> Added 8-bit support for eMMC for SD/MMC Renamed MPU Subsystem to Cortex-A9 MPCore*
2016.05.03	Maintenance release.
2015.11.02	Updated the link to the Memory Maps.
2015.05.04	Corrected the base address for NANDDATA in the "Peripheral Region Address Map" table.
2014.12.15	Maintenance release
2014.07.31	Updated address maps and register descriptions
2014.06.30	Maintenance release
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.3	Minor updates.
1.2	Updated address spaces section.
1.1	Added peripheral region address map.
1.0	Initial release.

[Introduction to the Hard Processor System](#) on page 2-1

Table 1-3: Clock Manager Revision History

Document Version	Changes
2020.01.13	Correct typical <code>sdmmc_clk</code> frequencies in <i>Flash Controller Clocks</i>
2015.11.02	Minor formatting updates.
2015.05.04	Minor formatting updates.
2014.12.15	FREE, FVCO, and FOUT Equations section updated. More information added about vco register, M and N equations. Reference Clock information added to Clock Groups section.
2014.06.30	E0SC1 changed to HPS_CLK1 E0SC2 changed to HPS_CLK2 Added Address Map and Register Descriptions
2014.02.28	Updated content in the "Peripheral Clock Group" section
2013.12.30	Minor formatting updates.
1.2	Minor updates.
1.1	<ul style="list-style-type: none"> • Reorganized and expanded functional description section. • Added address map and register definitions section.
1.0	Initial release.

[Clock Manager](#) on page 3-1

Table 1-4: Reset Manager Revision History

Document Version	Changes
2015.11.02	Updated "Reset Pins" section
2015.05.04	Updated: <ul style="list-style-type: none"> • MISC Group, Generated Module Resets table • "Reset Pins" section
2014.12.15	<ul style="list-style-type: none"> • Signal power information added to "HPS External Reset Sources" section • Updated block diagram with <code>h2f_dbg_rst_n</code> signal
2014.06.30	<ul style="list-style-type: none"> • Updated "Functional Description of Reset Manager" • Added address map and register descriptions

Document Version	Changes
2014.02.28	Updated sections: <ul style="list-style-type: none"> Reset Sequencing Warm Reset Assertion Sequence
2013.12.30	Minor formatting issues.
1.2	<ul style="list-style-type: none"> Added cold and warm reset timing diagrams.
1.1	Added reset controller, functional description, and address map and register definitions sections.
1.0	Initial release.

[Reset Manager](#) on page 4-1

Table 1-5: FPGA Manager Revision History

Document Version	Changes
2019.06.14	Corrected the <code>mse1</code> descriptions for encodings 0x0 through 0x2 and 0x4 to 0x6 in the <code>stat</code> register.
2015.11.02	Provided more information for the configuration schemes for the dedicated pins.
2015.05.04	Added information about FPPx32.
2014.12.15	Maintenance release
2014.06.30	Added address maps and register definitions
2014.02.28	Maintenance release
2013.12.30	Minor updates.
1.3	Minor updates.
1.2	Updated the FPGA configuration section.
1.1	<ul style="list-style-type: none"> Updated the configuration schemes table. Updated the FPGA configuration section. Added address map and register definitions section.
1.0	Initial release.

[FPGA Manager](#) on page 5-1

Table 1-6: System Manager Revision History

Version	Changes
2018.11.03	Modified <code>mode</code> register bitfield descriptions for clarity.
2018.07.17	Made the following changes to the Pin Mux Control Group register block: <ul style="list-style-type: none"> Removed MIXED2_IO0 through MIXED2_IO7 and added MIXED1_IO0 through MIXED1_IO7. Added note to MIXED1_IO21 to indicate that it does not apply to the F484 package. Added new registers in the Pin Mux Control Group for routing QSPI, SD/MMC, UART, I2C, CAN, and SPI signals to the FPGA.
2014.06.30	<ul style="list-style-type: none"> Added address map and register descriptions Updated ECC Parity Control CAN controller section added
2014.02.28	Maintenance release
2013.12.30	Maintenance release.
1.2	Minor updates.
1.1	Added functional description, address map and register definitions sections.
1.0	Initial release.

[System Manager](#) on page 6-1

Table 1-7: Scan Manager Revision History

Document Version	Changes
2016.05.03	Added a list of the HPS I/O pins that do not support boundary scan tests in the <i>Arm* JTAG-AP Scan Chains</i> section.
2015.11.02	Maintenance release
2015.05.04	Maintenance release
2014.12.15	Maintenance release
2014.06.30	Add address map and register definitions
2014.02.28	Update to "Scan Manager Block Diagram and System Integration" section
2013.12.30	Minor formatting issues
1.2	Added JTAG-AP descriptions.
1.1	Added block diagram and system integration, functional description, and address map and register definitions sections.

Document Version	Changes
1.0	Initial release.

[Scan Manager](#) on page 7-1

Table 1-8: System Interconnect Revision History

Document Version	Changes
2015.05.04	<ul style="list-style-type: none"> Reference AXI ID encoding in MPU chapter Add information about the SDRAM address space
2014.12.15	<ul style="list-style-type: none"> Minor correction to table in "Available Address Maps" Add detail to "L3 Address Space"
2014.06.30	<ul style="list-style-type: none"> Corrected master interconnect security properties for: <ul style="list-style-type: none"> Ethernet MAC ETR Added address map and register descriptions
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.2	Minor updates.
1.1	<ul style="list-style-type: none"> Added interconnect connectivity matrix. Rearranged functional description sections. Simplified address remapping section. Added address map and register definitions section.
1.0	Initial release.

[System Interconnect](#) on page 8-1

Table 1-9: HPS-FPGA Bridges Revision History

Document Version	Changes
2014.06.30	Added address maps and register definitions
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.1	Described GPV

Document Version	Changes
1.0	Initial release

[HPS-FPGA Bridges](#) on page 9-1

Table 1-10: Cortex-A9 Microprocessor Unit Subsystem Document Revision History

Document Version	Changes
2020.01.13	Added new section <i>Avoiding ACP Dependency Lockup</i>
2019.06.14	Added details about arbitration behavior in the SCU when the ACP is not being used in the <i>Implementation Details</i> of the <i>Snoop Control Unit</i> section,
2016.10.28	<ul style="list-style-type: none"> Added note to "AXI Master Configuration for ACP Access" section Added "Configuring <code>AxCACHE[3:0]</code> Sideband Signals" and "Configuring <code>AxUser[4:0]</code> Sideband Signals" subsections to the "AXI Master Configuration for ACP Access" section Added note in the "Implementation Details" subsection of the "ACP ID Mapper" section.
2016.05.03	Maintenance release
2015.11.02	<ul style="list-style-type: none"> Reordered "L2 Cache" subsections Renamed "ECC Support" L2 subsection to be "Single Event Upset Protection" Added "L2 Cache Parity" subsection in "L2 Cache" section
2015.05.04	Clarified EMAC0 and EMAC1 ACP Mapper IDs in the "HPS Peripheral Master Input IDs" table in the "HPS Peripheral Master Input IDs" section.
2014.12.15	<ul style="list-style-type: none"> Added bus transaction scenarios in the "Accelerator Coherency Port" section Added the "AxUSER and AxCACHE Attributes" subsection to the "Accelerator Coherency Port" section Added the "Shared Requests on ACP" subsection to the "Accelerator Coherency Port" section Added the "Configuration for ACP Use" subsection to the "Accelerator Coherency Port" section Clarified how to use fixed mapping mode in the ACP ID Mapper Updated HPS Peripheral Master Input IDs table Added a note to the "Control of the AXI User Sideband Signals" subsection in the "ACP ID Mapper" section. Added parity error handling information to the "L1 Caches" section and the "Cache Controller Configuration" topic of the "L2 Cache" section.
2014.06.30	<ul style="list-style-type: none"> Added Reset Section to Cortex-A9 Processor Updated HPS Peripheral Master Input IDs table Added ACP ID Mapper Address Map and Register Definitions Added information in ECC Support section regarding ECC errors Minor clarifications regarding MPU description and module revision numbers

Document Version	Changes
2014.02.28	Maintenance release
2013.12.30	Correct SDRAM region address in Arm Cortex-A9 MPCoreAddress Map
1.2	Minor updates.
1.1	<ul style="list-style-type: none"> Add description of the ACP ID mapper Consolidate redundant information
1.0	Initial release.

[Cortex-A9 Microprocessor Unit Subsystem](#) on page 10-1

Table 1-11: CoreSight Debug and Trace Revision History

Version	Changes
2014.07.31	Updated the address map and register definitions.
2014.06.30	Added address map and register definitions.
2014.02.28	Maintenance release.
2013.12.30	Maintenance release.
1.2	Minor updates.
1.1	Added functional description, programming model, and address map and register definition sections.
1.0	Initial release.

[CoreSight Debug and Trace](#) on page 11-1

Table 1-12: SDRAM Controller Subsystem Revision History

Document Version	Changes
2018.07.17	Modified text to clarify that there is support for up to 4 Gb external memory device per chip select.

Document Version	Changes
2015.11.02	<ul style="list-style-type: none"> Added information regarding calculation of ECC error byte address location from <code>erraddr</code> register in "User Notification of ECC Errors" section Added information regarding bus response to memory protection transaction failure in "Memory Protection" section Clarified "Protection" row in "Fields for Rules in Memory Protection" table in the "Memory Protection" section Clarified <code>protruledata.security</code> column in "Rules in Memory Protection Table for Example Configuration" table in the "Example of Configuration for TrustZone" section Added note about double-bit error functionality in "ECC Write Backs" subsection of "ECC" section Added the "DDR Calibration" subsection under "DDR PHY" section
2015.05.04	<ul style="list-style-type: none"> Added the recommended sequence for writing or reading a rule in the "Memory Protection" section.
2014.12.15	<ul style="list-style-type: none"> Added SDRAM Protection Access Flow Diagram to "Memory Protection" subsection in the "Single-Port Controller Operation" section. Changed the "SDRAM Multi-Port Scheduling" section to "SDRAM Multi-Port Arbitration" and added detailed information on how to use and program the priority and weighted arbitration scheme.
2014.6.30	<ul style="list-style-type: none"> Added <i>Port Mappings</i> section. Added <i>SDRAM Controller Memory Options</i> section. Enhanced <i>Example of Configuration for TrustZone</i> section. Added SDRAM Controller address map and registers.
2013.12.30	<ul style="list-style-type: none"> Added <i>Generating a Preloader Image for HPS with EMIF</i> section. Added <i>Debugging HPS SDRAM in the Preloader</i> section. Enhanced <i>Simulation</i> section.
1.1	Added address map and register definitions section.
1.0	Initial release.

SDRAM Controller Subsystem on page 12-1

Table 1-13: On-Chip Memory Revision History

Document Version	Changes
2018.01.26	Updated "On-Chip RAM Initialization" section with steps to enable ECC.
2016.10.28	Maintenance release
2016.05.03	Maintenance release
2015.11.02	Maintenance release
2015.05.04	Maintenance release

Document Version	Changes
2014.12.15	Maintenance release
2014.06.30	Added address maps and register definitions
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.1	Added address map section
1.0	Initial release

[On-Chip Memory](#) on page 13-1

Table 1-14: NAND Flash Controller Revision History

Document Version	Changes
2018.01.26	Updated "ECC Enabling" section with steps to enable ECC.
2016.10.28	Added content about the local memory buffer
2016.05.27	Added a link to the <i>Supported Flash Devices for Cyclone V and Arria V SoC</i> webpage.
2016.05.03	Maintenance release
2015.11.02	<ul style="list-style-type: none"> Moved "Interface Signals" section after "NAND Flash Controller Block Diagram and System Integration" section and renamed it to "NAND Flash Controller Signal Description" Updated the Interrupt and DMA Enabling section to recommend reading back a register to ensure clearing an interrupt status Specified the valid values for Burst Length in the Command-Data Pair 4 table Updated the description of <code>dma_cmd_comp</code> and added a RESERVED bit for <code>intr_status0/1/2/3</code> and <code>intr_en0/1/2/3</code>
2015.05.04	Added information about clearing out the ECC before the feature is enabled
2014.12.15	Maintenance release
2014.07.31	Updated address map and register definitions.
2014.06.30	<ul style="list-style-type: none"> Added address map and register definitions. Removed Command DMA section.
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.2	<ul style="list-style-type: none"> Supports one 8-bit device Show additional supported block sizes Bad block marker handling

Document Version	Changes
1.1	Added programming model section.
1.0	Initial release

[NAND Flash Controller](#) on page 14-1

Table 1-15: SD/MMC Controller Revision History

Version	Changes
2018.01.26	Added "Enabling ECC" section.
2017.12.27	Added 8-bit support for eMMC in the "Features of SD/MMC Controller" section. (FB320076)
2016.10.28	<ul style="list-style-type: none"> Removed SPI support in tables in the Features section Added 8-bit support for eMMC for SD/MMC
2016.05.27	Added a link to the <i>Supported Flash Devices for Cyclone V and Arria V SoC</i> webpage.
2016.05.03	Maintenance release.
2015.11.02	<ul style="list-style-type: none"> Moved "Interface Signals" section below "SD/MMC Controller Block Diagram and System Integration" section and renamed to "SD/MMC Signal Description." Clarified signals in this section. Added information that Card Detect is only supported on interfaces routed via the FPGA fabric.
2015.05.04	Added information about clearing out the ECC before the feature is enabled
2014.12.15	Maintenance release
2014.06.30	Added address maps and register definitions
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.1	<ul style="list-style-type: none"> Added programming model section. Reorganized programming information. Added information about ECCs. Added pin listing. Updated clocks section.
1.0	Initial release.

[SD/MMC Controller](#) on page 15-1

Table 1-16: Quad SPI Flash Controller Revision History

Document Version	Changes
2019.07.09	Maintenance release
2019.06.14	<ul style="list-style-type: none"> Added a new section, <i>Write Request</i>, with WREN and RDSR information Removed step 6 in <i>Indirect Write Operation with DMA Disabled</i> because it is unnecessary when DMA is disabled.
2018.01.26	Updated "Local Memory Buffer" section with steps to enable ECC.
2016.10.28	Maintenance release
2016.05.27	<ul style="list-style-type: none"> Changed the name of the internal QSPI reference clock from <code>qspi_clk</code> to <code>qspi_ref_clk</code>; and the external QSPI output clock, from <code>sclk_out</code> to <code>qspi_clk</code>. Added a link to the <i>Supported Flash Devices for Cyclone V and Arria V SoC</i> webpage. Re-worded information about disabling the watermark feature in the "Indirect Read Operation" and "Indirect Write Operation" sections.
2016.05.03	<ul style="list-style-type: none"> Added clarification for the SRAM indirect read and write size allocations. Updated the SRAM block on the "Quad SPI Flash Controller Block Diagram and System Integration" figure.
2015.11.02	<ul style="list-style-type: none"> Moved "Interface Signals" section below "Quad SPI Flash Controller Block Diagram and System Integration" Better defined <code>l4_mp_clk</code> clock. Updated step 11 in the "Setting Up the Quad SPI Flash Controller" for clarity.
2015.05.04	Added information about clearing out the ECC before the feature is enabled
2014.12.15	Maintenance release
2014.07.31	Updated address maps and register descriptions
2014.06.30	Added address maps and register definitions
2014.02.28	Maintenance release
2013.12.30	Maintenance release
1.2	Minor updates.
1.1	Added block diagram and system integration, functional description, programming model, and address map and register definitions sections.
1.0	Initial release.

[Quad SPI Flash Controller](#) on page 16-1

Table 1-17: DMA Controller Revision History

Document Version	Changes
2018.01.26	Updated "Initializing and Clearing of Memory before Enabling ECC" section with steps to enable ECC.
2016.10.28	Maintenance release
2016.05.03	Maintenance release
2015.11.02	<ul style="list-style-type: none"> Updated link point to the HPS Address Map and Register Definitions Added information about the instruction fetch cache properties Added a description about the relationship between the GIC interrupt map and INTCLR register
2015.05.04	<ul style="list-style-type: none"> Added Synopsys* handshake rules. Added information about the Bosch* CAN protocol.
2014.12.15	Maintenance release
2014.07.31	Updated address maps and register descriptions
2014.06.30	Added address maps and register definitions
2014.02.28	ECC updates
1.2	Maintenance release
1.1	Minor updates
1.0	Initial release

[DMA Controller](#) on page 17-1

Table 1-18: Ethernet Media Access Controller Revision History

Document Version	Changes
2019.06.14	<ul style="list-style-type: none"> Clarified the PCF bit description for encoding value 0x2 in the MAC_Frame_Filter register. Clarified "Busy Bit" (gb bit of GMII_Address register) in Flow_Control register description. Clarified that ttc bit resides in the Operation_Mode Register (Register 6). Clarified that the pcsancis and the pcslchgis bits of the Interrupt_Status register can be ignored because they apply to TBI, RTBI, or SGMII interface only.
2016.10.28	<ul style="list-style-type: none"> Note added into <i>PHY Interface</i> section Bit 16 updated Transmit Descriptor table
2016.05.03	Maintenance release.

Document Version	Changes
2015.11.02	<ul style="list-style-type: none"> Added the following subsections in the "Layer 3 and Layer 4 Filters" section: <ul style="list-style-type: none"> Layer 3 and Layer 4 Filters Register Set Layer 3 Filtering Layer 4 Filtering
2015.05.04	<ul style="list-style-type: none"> Corrected IEEE 1588 timestamp resolution in the "EMAC Block Diagram and System Integration" section and the "IEEE 1588-2002 Timestamps" section Added reset pulse width for <code>rst_clk_tx_n_o</code> and <code>rst_clk_rx_n_o</code> in the "FPGA EMAC I/O signals" section Added subsections "Ordinary Clock," "Boundary Clock," "End-to-End Transparent Clock" and "Peer-to-Peer Transparent Clock" in the "Clock Type" section
2014.12.15	<ul style="list-style-type: none"> Updated <i>EMAC Block Diagram and System Integration</i> section with new diagram and information. Added <i>Signal Descriptions</i> section. Added <i>EMAC Internal Interfaces</i> section. Added <i>TX FIFO</i> and <i>RX FIFO</i> subsection to the <i>Transmit and Receive Data FIFO Buffers</i> section. Updated <i>Descriptor Overview</i> section to clarify support for only enhanced (alternate) descriptors. Added <i>Destination and Source Address Filtering Summary</i> in <i>Frame Filtering</i> Section. Added <i>Clock Structure</i> sub-section to <i>Clocks and Resets</i> section Added <i>System Level EMAC Configuration Registers</i> section in <i>Ethernet Programming Model</i> Added <i>EMAC Interface Initialization for FPGA GMII/MII Mode</i> section in <i>Ethernet Programming Model</i> Added <i>EMAC Interface Initialization for RGMII/RMII Mode</i> section in <i>Ethernet Programming Model</i> Corrected <i>DMA Initialization</i> and <i>EMAC Initialization and Configuration</i> titles to appear on correct initialization information Removed duplicate programming information for DMA Added <i>Taking the Ethernet MAC Out of Reset</i> section.
2014.06.30	<p>Updated EMAC to RGMII Interface table with EMAC Port names</p> <p>Updated EMAC to FPGA PHY Interface table with Signal names</p> <p>Updated EMAC to FPGA IEEE1588 Timestamp Interface with Signal names</p> <p>Added Address Map and Register Descriptions</p>
2014.02.28	ECC updates.
1.4	Maintenance release.
1.3	<ul style="list-style-type: none"> Expanded shared memory block table. Added CSEL tables. Additional minor updates.
1.2	Updated the HPS boot and FPGA configuration sections.

Ethernet Media Access Controller on page 18-1**Table 1-19: USB 2.0 OTG Controller Revision History**

Document Version	Changes
2018.01.26	Added steps for enabling ECC.
2016.10.28	Maintenance release.
2016.05.03	Maintenance release.
2015.11.02	Renamed "ULPI PHY Interface" section to "USB 2.0 ULPI PHY Signal Description" and moved it after the "USB OTG Controller Block Diagram and System Integration" section.
2015.05.04	Maintenance release.
2014.12.15	<ul style="list-style-type: none"> • Maintenance release. • Added <i>Taking the USB OTG Out of Reset</i> section.
2014.07.31	Updated address map and register definitions.
2014.06.30	Added USB OTG Controller address map and register definitions.
2014.02.28	Maintenance release.
2013.12.30	Maintenance release.
1.2	<ul style="list-style-type: none"> • Described interrupt generation. • Described software initialization in host and device modes. • Described software operation in host and device modes. • Simplified features list. • Simplified hardware description.
1.1	Added information about ECCs.
1.0	Initial release.

USB 2.0 OTG Controller on page 19-1**Table 1-20: SPI Controller Revision History**

Version	Changes
2017.01.26	Corrected the support information for continuous data transfers in <i>SPI Serial Format</i> .
2016.10.28	Maintenance release.
2016.05.03	Maintenance release.

Version	Changes
2015.11.02	<ul style="list-style-type: none"> Renamed "Interface Pins" section to "Interface to HPS I/O" and moved it under the "SPI Controller Signal Description" section Moved "FPGA Routing" section under "SPI Controller Signal Description" section Added Multi-Master mode to "Features of the SPI Controller" section Updated "RXD Sample Delay" section Updated "SPI Slave" section Updated "Glue Logic for Master Port ss_in_n" section
2015.05.04	Maintenance release.
2014.12.15	<ul style="list-style-type: none"> Maintenance release. Added <i>Taking the SPI Out of Reset</i> section.
2014.06.30	<ul style="list-style-type: none"> "Glue Logic for Master Port ss_in_n" section added Interface Pins topic added FPGA Routing topic added Added address aap and register descriptions
2014.02.28	Maintenance release.
2013.12.30	Minor formatting updates.
1.2	Minor updates.
1.1	Added programming model, address map and register definitions, clocks, and reset sections.
1.0	Initial release.

[SPI Controller](#) on page 20-1

Table 1-21: I²C Controller Revision History

Document Version	Changes
2015.05.04	<ul style="list-style-type: none"> Added <i>Impact of SCL Rise Time and Fall Time On Generated SCL</i> figure to "Clock Synchronization" section Updated "Minimum High and Low Counts" section
2014.12.15	<ul style="list-style-type: none"> Maintenance release. Added <i>Taking the I²C Out of Reset</i> section.
2014.06.30	<p>HPS I²C Signals for FPGA Routing table updated</p> <p>I²C interface in FPGA Fabric diagram added</p> <p>Added Address Map and Register Descriptions</p>

Document Version	Changes
2014.02.28	Maintenance release.
2013.12.30	Added HPS I ² c Signals for FPGA routing to "Interface Pins" section.
1.2	Minor updates.
1.1	Added programming model, address map and register definitions, clocks, reset, and interface pins sections.
1.0	Initial release.

The Cyclone® V system-on-a-chip (SoC) is composed of two distinct portions- a single- or dual-core Arm Cortex-A9 hard processor system (HPS) and an FPGA. The HPS architecture integrates a wide set of peripherals that reduce board size and increase performance within a system.

The SoC features the FPGA I/O, which is I/O pins dedicated to the FPGA fabric.

Figure 2-1: Intel SoC Device Block Diagram

The HPS consists of the following types of modules:

- Microprocessor unit (MPU) subsystem with single or dual Arm Cortex-A9 MPCore processors
- Flash memory controllers
- SDRAM controller subsystem
- System interconnect
- On-chip memories
- Support peripherals
- Interface peripherals
- Debug components
- Phase-locked loops (PLLs)

Intel assumes no responsibility or liability arising out of the application or use of any information, product, or service described herein except as expressly agreed to in writing by Intel. Intel customers are advised to obtain the latest version of device specifications before relying on any published information and before placing orders for products or services.

*Other names and brands may be claimed as the property of others.

ISO
9001:2015
Registered

The HPS incorporates third-party intellectual property (IP) from several vendors.

The dual-processor HPS supports symmetric (SMP) and asymmetric (AMP) multiprocessing.

The FPGA portion of the device contains:

- FPGA fabric
- Control block (CB)
- PLLs
- High-speed serial interface (HSSI) transceivers, depending on the device variant
- Hard PCI Express* (PCI-e) controllers
- Hard memory controllers

The HPS and FPGA communicate with each other through bus interfaces that bridge the two distinct portions. On a power-on reset, the HPS can boot from multiple sources, including the FPGA fabric and external flash. The FPGA can be configured through the HPS or an externally supported device.

The HPS and FPGA portions of the device each have their own pins. Pins are not freely shared between the HPS and the FPGA fabric. The HPS I/O pins are configured by boot software executed by the MPU in the HPS. Software executing on the HPS accesses control registers in the system manager to assign HPS I/O pins to the available HPS modules. The FPGA I/O pins are configured by an FPGA configuration image through the HPS or any external source supported by the device.

The MPU subsystem can boot from flash devices connected to the HPS pins. When the FPGA portion is configured by an external source, the MPU subsystem can boot from flash memory devices available to the FPGA portion of the device.

The HPS and FPGA portions of the device have separate external power supplies and independently power on. You can power on the HPS without powering on the FPGA portion of the device. However, to power on the FPGA portion, the HPS must already be on or powered at the same time as the FPGA portion. You can also turn off the FPGA portion of the device while leaving the HPS power on.

Table 2-1: Valid SoC Power Modes

HPS	FPGA	Valid?
Off	Off	Yes
Off	On	No
On	Off	Yes
On	On	Yes

Features of the HPS

The main modules of the HPS are:

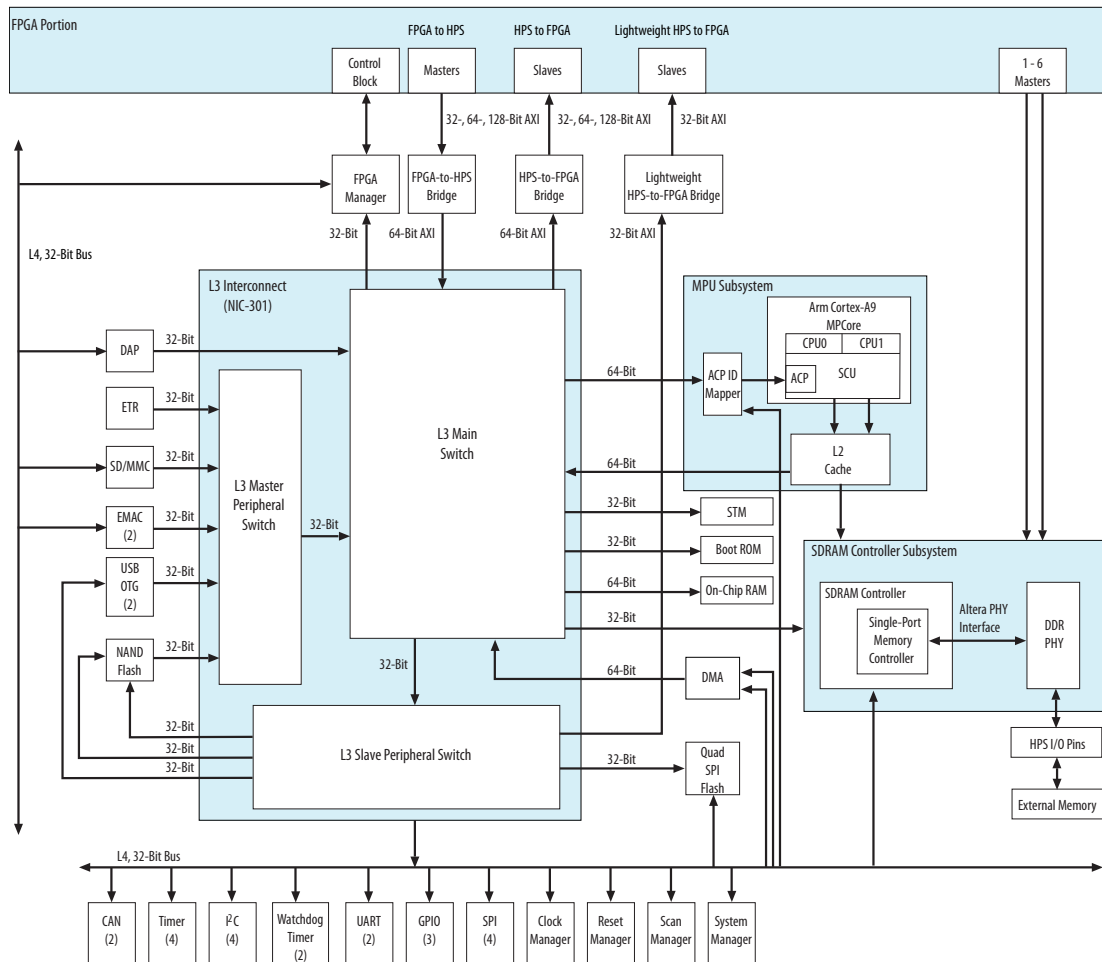

- MPU subsystem featuring a single- or dual-core Arm Cortex-A9 MPCore processor
- General-purpose direct memory access (DMA) controller
- Two ethernet media access controllers (EMACs)
- Two USB 2.0 on-the-go (OTG) controllers
- NAND flash controller
- Quad SPI flash controller
- Secure digital/multimedia card (SD/MMC) controller
- Two serial peripheral interface (SPI) master controllers
- Two SPI slave controllers
- Four inter-integrated circuit (I²C) controllers
- 64 KB on-chip RAM
- 64 KB on-chip boot ROM
- Two UARTs
- Four timers
- Two watchdog timers
- Three general-purpose I/O (GPIO) interfaces
- Two controller area network (CAN) controllers
- Arm CoreSight debug components:
 - Debug access port (DAP)
 - Trace port interface unit (TPIU)
 - System trace macrocell (STM)
 - Program trace macrocell (PTM)
 - Embedded trace router (ETR)
 - Embedded cross trigger (ECT)
- System manager
- Clock manager
- Reset manager
- Scan manager
- FPGA manager
- SDRAM controller subsystem

⁽¹⁾ Two of the four I²Cs, provide support for general purpose.

HPS Block Diagram and System Integration

HPS Block Diagram

Figure 2-2: HPS Block Diagram

Cortex-A9 MPCore

The MPU subsystem provides the following functionality:

- Arm Cortex-A9 MPCore
 - One or two Arm Cortex-A9 processors
 - NEON™ single instruction, multiple data (SIMD) coprocessor and vector floating-point v3 (VFPv3) per processor
 - Snoop control unit (SCU) to ensure coherency between processors
 - Accelerator coherency port (ACP) that accepts coherency memory access requests
 - Interrupt controller
 - One general-purpose timer and one watchdog timer per processor
 - Debug and trace features
 - 32 KB instruction and 32 KB data level 1 (L1) caches per processor
 - Memory management unit (MMU) per processor
- Arm L2-310 level 2 (L2) cache
 - Shared 512 KB L2 cache
- ACP ID mapper
 - Maps the 12-bit ID from the level 3 (L3) interconnect to the 3-bit ID supported by the ACP

A programmable address filter in the L2 cache controls which portions of the 32-bit physical address space can be accessed by each master.

Related Information

[HPS Block Diagram](#) on page 2-4

HPS Interfaces

The Cyclone V device family provides multiple communication channels to the HPS.

HPS-FPGA Memory-Mapped Interfaces

The HPS-FPGA memory-mapped interfaces provide the major communication channels between the HPS and the FPGA fabric. The HPS-FPGA memory-mapped interfaces include:

- FPGA-to-HPS bridge—a high-performance bus with a configurable data width of 32, 64, or 128 bits, allowing the FPGA fabric to master transactions to the slaves in the HPS. This interface allows the FPGA fabric to have full visibility into the HPS address space. This interface also provides access to the coherent memory interface
- HPS-to-FPGA bridge—a high-performance interface with a configurable data width of 32, 64, or 128 bits, allowing the HPS to master transactions to slaves in the FPGA fabric
- Lightweight HPS-to-FPGA bridge—an interface with a 32-bit fixed data width, allowing the HPS to master transactions to slaves in the FPGA fabric

Related Information

[HPS-FPGA Bridges](#) on page 9-1

Other HPS Interfaces

- TPIU trace—sends trace data created in the HPS to the FPGA fabric
- FPGA System Trace Macrocell (STM) —an interface that allows the FPGA fabric to send hardware events to be stored in the HPS trace data
- FPGA cross-trigger—an interface that allows the CoreSight trigger system to send triggers to IP cores in the FPGA, and vice versa
- DMA peripheral interface—multiple peripheral-request channels
- FPGA manager interface—signals that communicate with the FPGA fabric for boot and configuration
- Interrupts—allow soft IP cores to supply interrupts directly to the MPU interrupt controller
- MPU standby and events—signals that notify the FPGA fabric that the MPU is in standby mode and signals that wake up Cortex-A9 processors from a wait for event (WFE) state
- HPS debug interface – an interface that allows the HPS debug control domain (debug APB) to extend into FPGA

Other HPS-FPGA communications channels:

- FPGA clocks and resets
- HPS-to-FPGA JTAG—allows the HPS to master the FPGA JTAG chain

System Interconnect

The system interconnect consists of the main L3 interconnect and level 4 (L4) buses. The L3 interconnect is an Arm NIC-301 module composed of the following switches:

- L3 main switch
 - Connects the master, slaves, and other subswitches
 - Provides 64-bit switching capabilities
- L3 master peripheral switch
 - Connects master ports of peripherals with integrated DMA controllers to the L3 main switch
- L3 slave peripheral switch
 - Connects slave ports of peripherals to the L3 main switch

Related Information

[System Interconnect](#) on page 8-1

SDRAM Controller Subsystem

HPS and FPGA fabric masters have access to the SDRAM controller subsystem.

The SDRAM controller subsystem implements the following high-level features:

- Support for double data rate 2 (DDR2), DDR3, and low-power double data rate 2 (LPDDR2) devices
- Error correction code (ECC) support, including calculation, single-bit error correction and write-back, and error counters
- Fully-programmable timing parameter support for all JEDEC-specified timing parameters
- All ports support memory protection and mutual accesses
- FPGA fabric interface with up to six ports that can be combined for a data width up to 256-bits wide using Avalon-MM and AXI interfaces.

The SDRAM controller subsystem is composed of the SDRAM controller, DDR PHY, control and status registers and their associated interfaces.

Related Information

[SDRAM Controller Subsystem](#) on page 12-1

SDRAM Controller

The SDRAM controller contains a multiport front end (MPFE) that accepts requests from HPS masters and from soft logic in the FPGA fabric through the FPGA-to-HPS SDRAM interface.

The SDRAM controller offers the following features:

- Up to 4 GB address range
- 8-, 16-, and 32-bit data widths
- Optional ECC support
- Low-voltage 1.35V DDR3L and 1.2V DDR3U support
- Full memory device power management support
- Two chip selects (DDR2 and DDR3)

The SDRAM controller provides the following features to maximize memory performance:

- Command reordering (look-ahead bank management)
- Data reordering (out of order transactions)
- Deficit round-robin arbitration with aging for bandwidth management
- High-priority bypass for latency sensitive traffic

Related Information

[SDRAM Controller Subsystem](#) on page 12-1

DDR PHY

The DDR PHY interfaces the single port memory controller to the HPS memory I/O.

Related Information

[SDRAM Controller Subsystem](#) on page 12-1

On-Chip Memory

On-Chip RAM

The on-chip RAM offers the following features:

- 64 KB size
- 64-bit slave interface
- High performance for all burst lengths

Related Information

[On-Chip Memory](#) on page 13-1

Boot ROM

The boot ROM offers the following features:

- 64 KB size
- Contains the code required to support HPS boot from cold or warm reset
- Used exclusively for booting the HPS

Related Information

- [On-Chip Memory](#) on page 13-1
- [Booting and Configuration](#) on page 31-1

Flash Memory Controllers

NAND Flash Controller

The NAND flash controller is based on the Cadence® Design IP® NAND Flash Memory Controller and offers the following functionality and features:

- Supports one x8 NAND flash device
- Supports Open NAND Flash Interface (ONFI) 1.0
- Supports NAND flash memories from Hynix, Samsung, Toshiba, Micron, and ST Micro
- Supports programmable 512 byte (4-, 8-, or 16-bit correction) or 1024 byte (24-bit correction) ECC sector size
- Supports pipeline read-ahead and write commands for enhanced read/write throughput
- Supports devices with 32, 64, 128, 256, 384, or 512 pages per block
- Supports multiplane devices
- Supports page sizes of 512 bytes, 2 kilobytes (KB), 4 KB, or 8 KB
- Supports single-level cell (SLC) and multi-level cell (MLC) devices with programmable correction capabilities
- Provides internal DMA
- Provides programmable access timing

Related Information

[NAND Flash Controller](#) on page 14-1

Quad SPI Flash Controller

The quad SPI flash controller is based on the Cadence Quad SPI Flash Controller and offers the following features:

- Supports SPIx1, SPIx2, or SPIx4 (Quad SPI) serial NOR flash devices
- Supports direct access and indirect access modes
- Supports single, dual, and quad I/O instructions
- Support up to four chip selects
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Support eXecute-In-Place (XIP) mode
- Programmable baud rate generator to generate device clocks

Related Information

[Quad SPI Flash Controller](#) on page 16-1

SD/MMC Controller

The Secure Digital (SD), Multimedia Card (MMC), (SD/MMC) and CE-ATA host controller is based on the Synopsys DesignWare* Mobile Storage Host controller and offers the following features:

- Integrated descriptor-based DMA
- Supports CE-ATA digital protocol commands
- Supports single card
- Single data rate (SDR) mode only
- Programmable card width: 1-, 4-, and 8-bit
- Programmable card types: SD, SDIO, or MMC
- Up to 64 KB programmable block size
- Supports the following standards and card types:
 - SD, including eSD—version 3.0⁽²⁾
 - SDIO, including embedded SDIO (eSDIO)—version 3.0⁽³⁾
 - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41⁽⁴⁾
 - MMC: 1-bit data bus
 - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
 - MMCMobile: 1-bit data bus
 - MMCPlus: 1-bit, 4-bit, and 8-bit data bus
 - Default speed and high speed
- Supports embedded MMC (eMMC) version 4.41⁽⁵⁾
 - 1-bit, 4-bit and 8-bit data bus

Note: For an inclusive list of the programmable card types and versions supported, refer to the *SD/MMC Controller* chapter.

Related Information

[SD/MMC Controller](#) on page 15-1

Support Peripherals

Clock Manager

The clock manager offers the following features:

- Manages clocks for HPS
- Supports dynamic clock tuning

Related Information

[Clock Manager](#) on page 3-1

⁽²⁾ Does not support SDR50, SDR104, and DDR50 modes.

⁽³⁾ Does not support SDR50, SDR104, and DDR50 modes.

⁽⁴⁾ Does not support DDR mode.

⁽⁵⁾ Does not support DDR mode.

Reset Manager

The reset manager manages both hardware and software reset sources in the HPS. Reset status is also provided. Reset types include cold, warm, and debug. Reset behavior depends on the type.

Related Information

[Reset Manager](#) on page 4-1

System Manager

The system manager controls system functions and modules that need external control signals. The system manager offers the following features:

- ECC monitoring and control
- Low-level control of peripheral features not accessible through the control and status registers (CSRs)
- Freeze controller that places I/O elements into a safe state for configuration

Related Information

[System Manager](#) on page 6-1

Scan Manager

The scan manager is used to configure and manage HPS I/O pins and to communicate with the FPGA JTAG.

Related Information

[Scan Manager](#) on page 7-1

Timers

The four timers are based on the Synopsys DesignWare APB Timer peripheral and offer the following features:

- 32-bit timer resolution
- Free-running timer mode
- Supports a time-out period of up to 43 seconds when the timer clock frequency is 100 MHz
- Interrupt generation

Related Information

[Timer](#) on page 24-1

Watchdog Timers

The two watchdog timers are based on the Synopsys DesignWare APB Watchdog Timer peripheral and offer the following features:

- 32-bit timer resolution
- Interrupt request
- Reset request
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)

Related Information

[Watchdog Timer](#) on page 25-1

DMA Controller

The DMA controller provides high-bandwidth data transfers for modules without integrated DMA controllers. The DMA controller is based on the Arm Corelink* DMA Controller (DMA-330) and offers the following features:

- Micro-coded to support flexible transfer types
 - Memory-to-memory
 - Memory-to-peripheral
 - Peripheral-to-memory
 - Scatter-gather
- Supports up to eight channels
- Supports flow control with 31 peripheral handshake interfaces
- Software can schedule up to 16 outstanding read and 16 outstanding write instructions
- Supports nine interrupt lines: one for DMA thread abort and eight for external events

Related Information

[DMA Controller](#) on page 17-1

FPGA Manager

The FPGA manager offers the following features:

- Manages configuration of the FPGA portion of the device
- 32-bit fast passive parallel configuration interface to the FPGA CSS block
- Partial reconfiguration
- Compressed FPGA configuration images
- Advanced Encryption Standard (AES) encrypted FPGA configuration images
- Monitors configuration-related signals in FPGA
- Provides 32 general-purpose inputs and 32 general-purpose outputs to the FPGA fabric

Related Information

[FPGA Manager](#) on page 5-1

Interface Peripherals

EMACs

The two EMACs are based on the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC and offer the following features:

- Supports 10, 100, and 1000 Mbps standard
- Integrated DMA controller
- Supports the PHY interfaces using the HPS I/O pins:
 - Reduced gigabit media independent interface (RGMI)
- Supports the PHY interfaces using adaptor logic to route signals to the FPGA I/O pins:
 - Media independent interface (MII)
 - Gigabit media independent interface (GMII)
 - Reduced gigabit media independent interface (RGMII)
 - Serial gigabit media independent interface (SGMII) supported through the GMII to FPGA fabric with additional external conversion logic

- The Ethernet Controller has two choices for the management control interface used for configuration and status monitoring of the PHY
 - Management data input/output (MDIO)
 - I²C PHY management through a separate I²C module within the HPS
- Supports IEEE 1588-2002 and IEEE 1588-2008 standards for precision networked clock synchronization
- IEEE 802.3-az, version D2.0 of Energy Efficient Ethernet
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Supports a variety of address filtering modes

Related Information

[Ethernet Media Access Controller](#) on page 18-1

USB Controllers

The HPS provides two USB 2.0 Hi-Speed On-the-Go (OTG) controllers from Synopsys DesignWare. The USB controller signals cannot be routed to the FPGA like those of other peripherals; instead they are routed to the dedicated I/O.

Each of the USB controllers offers the following features:

- Complies with the following specifications:
 - USB OTG Revision 1.3
 - USB OTG Revision 2.0
 - Embedded Host Supplement to the USB Revision 2.0 Specification
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported; however, in device mode, only high speed and full speed are supported.

- Local buffering with Error Correction Code (ECC) support

Note: The USB 2.0 OTG controller does not support the following interface standards:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)
- Supports USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) PHYs (SDR mode only)
- Supports up to 16 bidirectional endpoints, including control endpoint 0

Note: Only seven periodic device IN endpoints are supported.

- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.

- Supports generic root hub
- Supports automatic ping capability

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website.

I²C Controllers

The four I²C controllers are based on Synopsys DesignWare APB I²C controller which offer the following features:

- Two controllers support I²C management interfaces for use by the EMAC controllers
- Support both 100 KBps and 400 KBps modes
- Support both 7-bit and 10-bit addressing modes
- Support master and slave operating mode
- Direct access for host processor
- DMA controller may be used for large transfers

Related Information

[I2C Controller](#) on page 21-1

UARTs

The HPS provides two UART controllers to provide asynchronous serial communications. The two UART modules are based on Synopsys DesignWare APB Universal Asynchronous Receiver/ Transmitter peripheral and offer the following features:

- 16550-compatible UART
- Support automatic flow control as specified in 16750 standard
- Programmable baud rate up to 6.25 MBaud (with 100MHz reference clock)
- Direct access for host processor
- DMA controller may be used for large transfers
- 128-byte transmit and receive FIFO buffers

Related Information

[UART Controller](#) on page 22-1

CAN Controllers

The two CAN controllers are based on the Bosch D_CAN controller and offer the following features:

- Compliant with CAN protocol specification 2.0 part A & B
- Programmable communication rate up to 1 Mbps
- Holds up to 128 messages
- Supports 11-bit standard and 29-bit extended identifiers
- Programmable interrupt scheme
- Direct access for host processor
- DMA controller may be used for large transfers

Related Information

[CAN Controller](#) on page 26-1

SPI Master Controllers

The two SPI master controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and offer the following features:

- Choice of Motorola* SPI, Texas Instruments* Synchronous Serial Protocol or National Semiconductor* Microwire protocol
- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Supports up to four chip selects
- Direct access for host processor
- DMA controller may be used for large transfers
- Programmable master serial bit rate
- Support for `rx_d` sample delay
- Transmit and receive FIFO buffers are 256 words deep

Related Information

[SPI Controller](#) on page 20-1

SPI Slave Controllers

The two SPI slave controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and offer the following features:

- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Direct access for host processor
- DMA controller may be used for large transfers
- Transmit and receive FIFO buffers are 256 words deep

Related Information

[SPI Controller](#) on page 20-1

GPIO Interfaces

The HPS provides three GPIO interfaces that are based on Synopsys DesignWare APB General Purpose Programming I/O peripheral and offer the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 67 dedicated I/O pins and an additional 14 input-only pins

Related Information

[General-Purpose I/O Interface](#) on page 23-1

CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate PTM for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP cores to generate of triggers and system trace messages
- Custom message injection through STM into trace stream for delivery to host debugger
- Capability to route trace data to any slave accessible to the ETR master, which is connected to the level 3 (L3) interconnect

Related Information

[CoreSight Debug and Trace](#) on page 11-1

Endian Support

The HPS is natively a little-endian system. All HPS slaves are little endian.

The processor masters are software configurable to interpret data as little endian, big endian, or byte-invariant (BE8). All other masters, including the USB 2.0 interface, are little endian. Registers in the MPU and L2 cache are little endian regardless of the endian mode of the CPUs.

Note: Intel strongly recommends that you only use little endian.

The FPGA-to-HPS, HPS-to-FPGA, FPGA-to-SDRAM, and lightweight HPS-to-FPGA interfaces are little endian.

If a processor is set to BE8 mode, software must convert endianness for accesses to peripherals and DMA linked lists in memory. The processor provides instructions to swap byte lanes for various sizes of data.

The Arm Cortex-A9 MPU supports a single instruction to change the endianness of the processor and provides the REV and REV16 instructions to swap the endianness of bytes or half-words respectively. The MMU page tables are software configurable to be organized as little-endian or BE8.

The Arm DMA controller is software configurable to perform byte lane swapping during a transfer.

Introduction to the Hard Processor System Address Map

The address map specifies the addresses of slaves, such as memory and peripherals, as viewed by the MPU and other masters. The HPS has multiple address spaces, defined in the following section.

Related Information

[System Interconnect](#) on page 8-1

HPS Address Spaces

The following table shows the HPS address spaces and their sizes.

Address spaces are divided into one or more nonoverlapping regions. For example, the MPU address space has the peripheral, FPGA slaves, SDRAM window, and boot regions.

The following figure shows the relationships between the HPS address spaces. The figure is not to scale.

Figure 2-3: HPS Address Space Relationships

The window regions provide access to other address spaces. The thin black arrows indicate which address space is accessed by a window region (arrows point to accessed address space). For example, accesses to the ACP window in the L3 address space map to a 1 GB region of the MPU address space.

The SDRAM window in the MPU address space can grow and shrink at the top and bottom (short, blue vertical arrows) at the expense of the FPGA slaves and boot regions. For specific details, refer to “MPU Address Space”.

The ACP window can be mapped to any 1 GB region in the MPU address space (blue vertical bidirectional arrow), on gigabyte-aligned boundaries.

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

Table 2-2: Common Address Space Regions

Region Name	Base Address	Size
FPGA slaves	0xC0000000	960 MB
Peripheral	0xFC000000	64 MB
Lightweight FPGA slaves	0xFF200000	2 MB

SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-HPS SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces can be configured at runtime.

Related Information

[System Interconnect](#) on page 8-1

For more information about how to configure SDRAM address space.

MPU Address Space

The MPU address space is 4 GB and applies to addresses generated inside the MPU.

The MPU address space contains the following regions:

- The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space.

The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries. The boundaries are megabyte-aligned. Addresses within the boundaries route to the SDRAM master. Addresses outside the boundaries route to the system interconnect master.

Related Information

The hard processor system (HPS) clock generation is centralized in the clock manager. The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. Clocks are organized in clock groups. A clock group is a set of clock signals that originate from the same clock source. A phase-locked loop (PLL) clock group is a clock group where the clock source is a common PLL voltage-controlled oscillator (VCO).

Features of the Clock Manager

The *Clock Manager* offers the following features:

- Generates and manages clocks in the HPS
- Contains the following PLL clock groups:
 - PLL 0 (Main)—contains clocks for the Cortex-A9 microprocessor unit (MPU) subsystem, level 3 (L3) interconnect, level 4 (L4) peripheral bus, and debug
 - PLL 1 (Peripheral)—contains clocks for PLL-driven peripherals
 - SDRAM—contains clocks for the SDRAM subsystem
- Allows scaling of the MPU subsystem clocks without disabling peripheral and SDRAM clock groups
- Generates clock gate controls for enabling and disabling most clocks
- Initializes and sequences clocks for the following events:
 - Cold reset
 - Safe mode request from reset manager on warm reset
- Allows software to program clock characteristics, such as the following items discussed later in this chapter:
 - Input clock source for SDRAM and peripheral PLLs
 - Multiplier range, divider range, and six post-scale counters for each PLL
 - Output phases for SDRAM PLL outputs
 - VCO enable for each PLL
 - Bypass modes for each PLL
 - Gate off individual clocks in all PLL clock groups
 - Clear loss of lock status for each PLL
 - Safe mode for Hardware-Managed clocks
 - General-purpose I/O (GPIO) debounce clock divide

ALTERA
now part of Intel

- Allows software to observe the status of all writable registers
- Supports interrupting the MPU subsystem on PLL-lock and loss-of-lock
- Supports clock gating at the signal level

The clock manager is **not** responsible for the following functional behaviors:

- Selection or management of the clocks for the FPGA-to-HPS and HPS-to-FPGA interfaces. The FPGA logic designer is responsible for selecting and managing these clocks.
- Software must not program the clock manager with illegal values. If it does, the behavior of the clock manager is undefined and could stop the operation of the HPS. The only guaranteed means for recovery from an illegal clock setting is a cold reset.
- When re-programming clock settings, there are no automatic glitch-free clock transitions. Software must follow a specific sequence to ensure glitch-free clock transitions. Refer to *Hardware-Managed and Software-Managed Clocks* section of this chapter.

Clock Manager Block Diagram and System Integration

Figure 3-1: Clock Manager Block Diagram

The following figure shows the major components of the clock manager and its integration in the HPS.

L4 Peripheral Clocks

The L4 peripheral clocks, denoted by `l4_mp_clk`, range up to 200 MHz.

Table 3-1: Clock List

Peripheral	Clock Name	Description
USB OTG 0/1 ⁽⁶⁾	hclk	AHB* clock
	pmu_hclk	PMU AHB clock. pmu_hclk is the scan clock for the PMU's AHB domain. Note: Select it as a test clock.
	utmi_clk	Always used as the PHY domain clock during DFT Scan mode. Note: Select utmi_clk as a test clock even when the core is configured for a non-UTMI PHY.
Quad SPI Flash Controller ⁽⁶⁾	pclk	APB clock
	hclk	AHB clock
NAND Flash Controller (Locally gated nand_mp_clk.) ⁽⁶⁾	ACLK	AHB Data port clock
	mACLK	AXI* Master port clock
	regACLK	AHB Register port clock
	ecc_clk	ECC circuitry clock
	clk_x	Bus Interface Clock
EMAC 0/1	aclk	Application clock for DMA AXI bus and CSR APB bus.
SD/MMC Controller	sdmmc_clk	All registers reside in the BIU clock domain.

For more information about the specific peripheral clocks, refer to their respective chapters.

⁽⁶⁾ Clock manager provides CSR bits for software enables to some peripherals. These enables are defaulted to enable. In boot mode, these enables are automatically active to ensure all clocks are active if RAM is cleared for security.

Functional Description of the Clock Manager

Clock Manager Building Blocks

PLLs

The clock manager contains three PLLs: PLL 0 (main), PLL 1 (peripherals), and SDRAM. These PLLs generate the majority of clocks in the HPS. There is no phase between the clocks generated by the three PLLs.

Each PLL has the following features:

- Phase detector and output lock signal generation
- Registers to set VCO frequency
 - (M) Multiplier range is 1 to 4096
 - (N) Divider range is 1 to 64
- Six post-scale counters (C0-C5) with a range of 1 to 512
- PLL can be enabled to bypass all outputs to the `osc1_clk` clock for glitch-free transitions

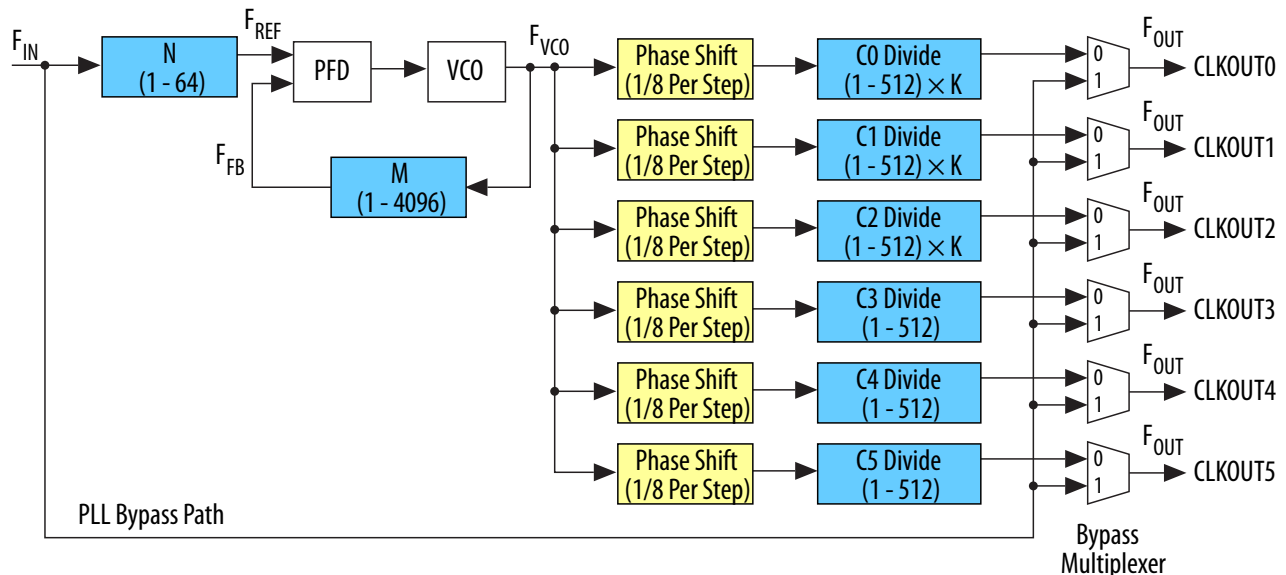

The SDRAM PLL has the following additional feature:

- Phase shift of 1/8 per step
 - Phase shift range is 0 to 7

FREF, FVCO, and FOUT Equations

Figure 3-2: PLL Block Diagram

Values listed for M, N, and C are actually one greater than the values stored in the CSRs.

$$F_{REF} = F_{IN} / N$$

$$FVCO = F_{REF} \times M = F_{IN} \times M/N$$

$$FOUT = F_{VCO} / (C_i \times K) = F_{REF} \times M / (C_i \times K) = (F_{IN} \times M) / (N \times C_i \times K)$$

Table 3-2: FREF, FVCO, and FOUT Equation variables

Variable	Value	Description
FVC	= VCO frequency	-
FIN	= Input frequency	-
FREF	= Reference frequency	-
C _i	= Post-scale counter	i is 0-5 for each of the six counters
K	= Internal post-scale counter in main PLL	reset values are K = 2 for C0 K=4 for C1 and C2
M	= numer + 1	Part of clock feedback path. VCO register is used to program M value. (Range 1 to 4096)
N	= denom + 1	Part of input clock path. VCO register is used to program N value. (Range 0 to 64)

Note: The reset values of numer and denom are 1 so that at reset, the M value is 2 and the N value is 2.

The vco register is used to program the M and N values. In the table below you can see which sections of the vco bit field are used to set the values of M and N.

Table 3-3: VCO Register

Name	Bit	Reset	Range	Description
numer	3:15	0x1	0 to 4095	Numerator in VCO output frequency equation. Note: Bit 15 reserved.
denom	16:21	0x1	0 to 63	Denominator in VCO output frequency equation.

Unused clock outputs should be set to a safe frequency such as 50 MHz to reduce power consumption and improve system stability.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 3-23

For the full bit field of the vco register, refer to the Address Map and Register Definitions section.

Dividers

Dividers subdivide the C0-C15 clocks produced by the PLL to lower frequencies. The main PLL C0-C2 clocks have an additional internal post-scale counter.

Clock Gating

Clock gating enables and disables clock signals. Refer to the Peripheral PLL Group Enable Register (*en*) for more information on what clocks can be gated.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 3-23

Control and Status Registers

The *Clock Manager* contains registers used to configure and observe the clock manager.

Hardware-Managed and Software-Managed Clocks

When changing values on clocks, the terms hardware-managed and software-managed define who is responsible for successful transitions. Software-managed clocks require that software manually gate any clock affected by the change, wait for any PLL lock if required, then ungate the clocks. Hardware-managed clocks use hardware to ensure that a glitch-free transition to a new clock value occurs. There are three hardware-managed sets of clocks in the HPS, namely, clocks generated from the main PLL outputs C0, C1, and C2. All other clocks in the HPS are software-managed clocks.

Clock Groups

The clock manager contains one clock group for each PLL and one clock group for the `HPS_CLK1` pin.

`HPS_CLK1` and `HPS_CLK2` are powered by the HPS reset and clock input pins power supply ($V_{CCRSTCLK_HPS}$). For more information on $V_{CCRSTCLK_HPS}$ refer to the Cyclone V Device Datasheet.

OSC1 Clock Group

The clock in the OSC1 clock group is derived directly from the `HPS_CLK1` pin. This clock is never gated or divided.

`HPS_c1k1` is used as a PLL input and also by HPS logic that does not operate on a clock output from a PLL.

Table 3-4: OSC1 Clock Group Clock

Name	Frequency	Clock Source	Destination
<code>osc1_clk</code>	10 to 50 MHz	<code>HPS_CLK1</code> pin	OSC1-driven peripherals. Refer to "Main Clock Group Clocks".

Main Clock Group

The main clock group consists of a PLL, dividers, and clock gating. The clocks in the main clock group are derived from the main PLL. The main PLL is always sourced from the `HPS_CLK1` pin of the device.

Table 3-5: Main PLL Output Assignments

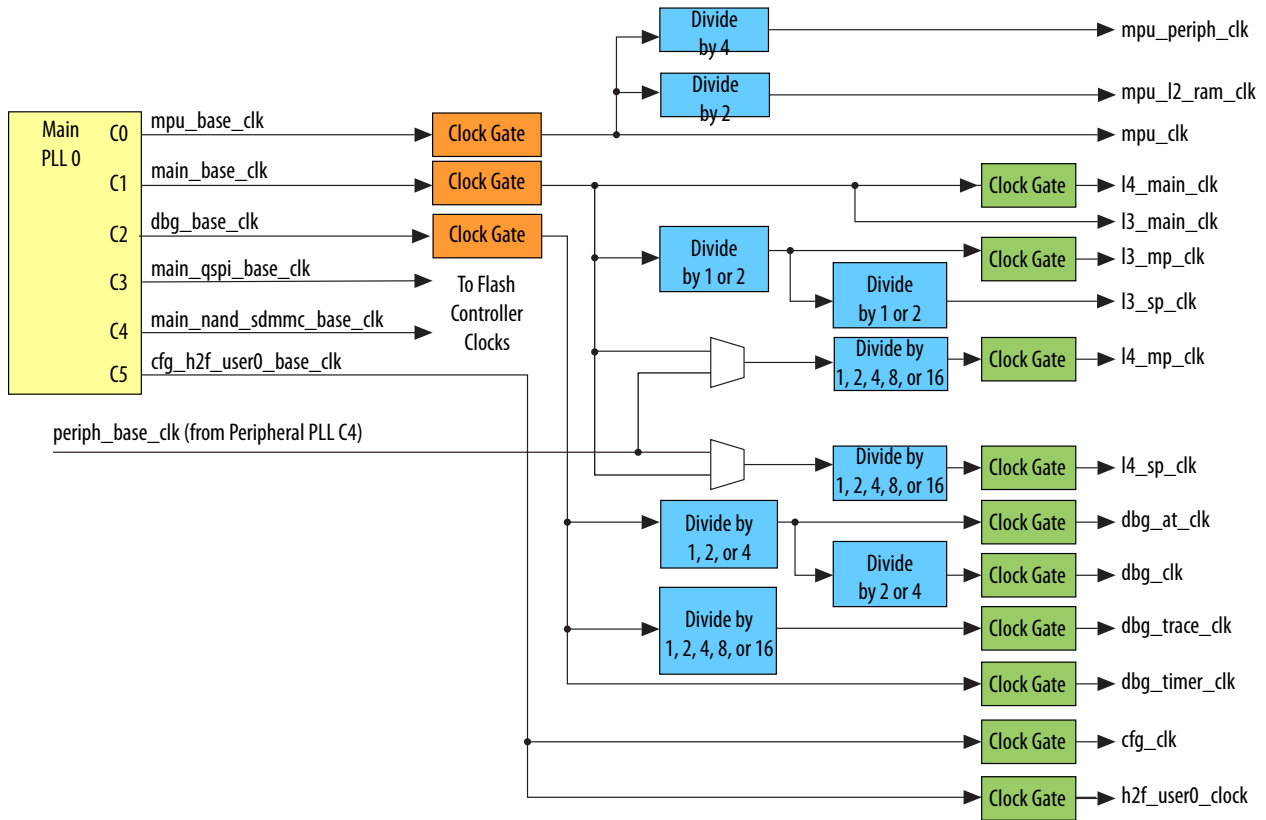

PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
Main	C0	mpu_base_clk	osc1_clk to varies (7)	No
	C1	main_base_clk	osc1_clk to varies (7)	No
	C2	dbg_base_clk	osc1_clk/4 to mpu_base_clk/2	No
	C3	main_qspi_base_clk	Up to 432 MHz	No
	C4	main_nand_sdmmc_base_clk	Up to 250 MHz for the NAND flash controller and up to 200 MHz for the SD/MMC controller	No
	C5	cfg_h2f_user0_base_clk	osc1_clk to 125 MHz for driving configuration and 100 MHz for the user clock	No

The counter outputs from the main PLL can have their frequency further divided by programmable dividers external to the PLL. Transitions to a different divide value occur on the fastest output clock, one clock cycle prior to the slowest clock's rising edge. For example the clock transitions on cycle 15 of the divide-by-16 divider for the main C2 output and cycle 3 of the divide-by-4 divider for the main C0 output.

The following figure shows how each counter output from the main PLL can have its frequency further divided by programmable post-PLL dividers. Green-colored clock gating logic is directly controlled by software writing to a register. Orange-colored clock gating logic is controlled by hardware. Orange-colored clock gating logic allows hardware to seamlessly transition a synchronous set of clocks, for example, all the MPU subsystem clocks.

⁽⁷⁾ The maximum frequency depends on the speed grade of the device.

Figure 3-3: Main Clock Group Divide and Gating

The clocks derived from main PLL C0-C2 outputs are hardware-managed, meaning hardware ensures that a clean transition occurs, and can have the following control values changed dynamically by software write accesses to the control registers:

- PLL bypass
- PLL numerator, denominator, and counters
- External dividers

For these registers, hardware detects that the write has occurred and performs the correct sequence to ensure that a glitch-free transition to the new clock value occurs. These clocks can pause during the transition.

Table 3-6: Main Clock Group Clocks

System Clock Name	Frequency	Constraints and Notes
mpu_clk	Main PLL C0	Clock for MPU subsystem, including CPU0 and CPU1
mpu_l2_ram_clk	mpu_clk/2	Clock for MPU level 2 (L2) RAM

System Clock Name	Frequency	Constraints and Notes
mpu_periph_clk	mpu_clk/4	Clock for MPU snoop control unit (SCU) peripherals, such as the general interrupt controller (GIC)
l3_main_clk	Main PLL C1	Clock for L3 main switch
l3_mp_clk	l3_main_clk/2	Clock for L3 master peripherals (MP) switch
l3_sp_clk	l3_mp_clk or l3_mp_clk/2	Clock for L3 slave peripherals (SP) switch
l4_main_clk	Main PLL C1	Clock for L4 main bus
l4_mp_clk	osc1_clk/16 to 100 MHz divided from main PLL C1 or peripheral PLL C4	Clock for L4 MP bus
l4_sp_clk	osc1_clk/16 to 100 MHz divided from main PLL C1 or peripheral PLL C4	Clock for L4 SP bus
dbg_at_clk	osc1_clk/4 to main PLL C2/2	Clock for CoreSight™ debug trace bus
dbg_trace_clk	osc1_clk/16 to main PLL C2	Clock for CoreSight™ debug Trace Port Interface Unit (TPIU)
dbg_timer_clk	osc1_clk to main PLL C2	Clock for the trace timestamp generator
dbg_clk (8)	dbg_at_clk/2 or dbg_at_clk/4	Clock for Debug Access Port (DAP) and debug peripheral bus
main_qspi_clk	Main PLL C3	Quad SPI flash internal logic clock
main_nand_sdmmc_clk	Main PLL C4	Input clock to flash controller clocks block
cfg_clk	osc1_clk to 100_MHz divided from main PLL C5	FPGA manager configuration clock

(8) dbg_clk must be at least twice as fast as the JTAG clock.

System Clock Name	Frequency	Constraints and Notes
h2f_user0_clock	osc1_clk to 100_MHz divided from main PLL C5	Auxiliary user clock to the FPGA fabric

Changing Values That Affect Main Clock Group PLL Lock

To change any value that affects the VCO lock of the main clock group PLL including the hardware-managed clocks, software must put the main PLL in bypass mode, which causes all the main PLL output clocks to be driven by the `osc1_clk` clock. Software must detect PLL lock by reading the lock status register prior to taking the main PLL out of bypass mode.

Once a PLL is locked, changes to any PLL VCO frequency that are 20 percent or less do not cause the PLL to lose lock. Iteratively changing the VCO frequency in increments of 20 percent or less allow a slow ramp of the VCO base frequency without loss of lock. For example, to change a VCO frequency by 40% without losing lock, change the frequency by 20%, then change it again by 16.7%.

Peripheral Clock Group

The peripheral clock group consists of a PLL, dividers, and clock gating. The clocks in the peripheral clock group are derived from the peripheral PLL. The peripheral PLL can be programmed to be sourced from the `HPS_CLK1` pin, the `HPS_CLK2` pin, or the `f2h_periph_ref_clk` clock provided by the FPGA fabric.

The FPGA fabric must be configured with an image that provides the `f2h_periph_ref_clk` before selecting it as the clock source. If the FPGA must be reconfigured and `f2h_periph_ref_clk` is being used by modules in the HPS, an alternate clock source must be selected prior to reconfiguring the FPGA.

Clocks that always use the peripheral PLL output clocks as the clocks source are:

- `emac0_clk`
- `emac1_clk`
- `usb_mp_clk`
- `spi_m_clk`
- `can0_clk`
- `can1_clk`
- `gpio_db_clk`
- `h2f_user1_clk`

In addition, clocks that may use the peripheral PLL output clocks as the clock source are:

- `sdmmc_clk`
- `nand_clk`
- `qspi_clk`
- `l4_mp_clk`
- `l4_sp_clk`

The counter outputs from the main PLL can have their frequency further divided by external dividers. Transitions to a different divide value occur on the fastest output clock, one clock cycle prior to the slowest clock's rising edge. For example, the clock transitions on cycle 15 of the divide-by-16 divider for the main C2 output and cycle 3 of the divide-by-4 divider for the C1 output.

Table 3-7: Peripheral PLL Output Assignments

PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
Peripheral	C0	emac0_base_clk	Up to 250 MHz	No
	C1	emac1_base_clk	Up to 250 MHz	No
	C2	periph_qspi_base_clk	Up to 432 MHz	No
	C3	periph_nand_sdmmc_base_clk	Up to 250 MHz for the NAND flash controller and up to 200 MHz for the SD/MMC controller	No
	C4	periph_base_base_clk	Up to 240 MHz for the SPI masters and up to 200 MHz for the scan manager	No
	C5	h2f_user1_base_clk	osc1_clk to 100 MHz	No

The following figure shows programmable post-PLL dividers and clock gating for the peripheral clock group. Clock gate blocks in the diagram indicate clocks that may be gated off under software control. Software is expected to gate these clocks off prior to changing any PLL or divider settings that might create incorrect behavior on these clocks.

Figure 3-4: Peripheral Clock Group Divide and Gating

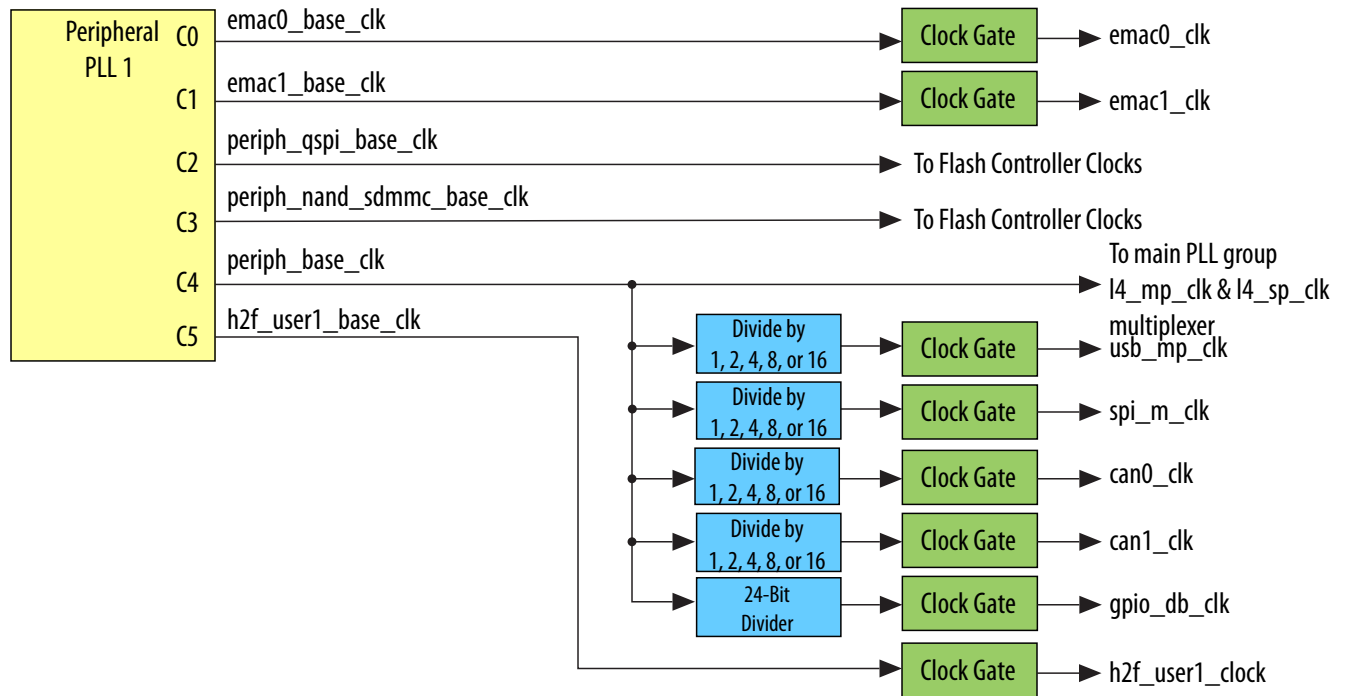

Table 3-8: Peripheral Clock Group Clocks

System Clock Name	Frequency	Divided From	Constraints and Notes
usb_mp_clk	Up to 200 MHz	Peripheral PLL C4	Clock for USB
spi_m_clk	Up to 240 MHz for the SPI masters and up to 200 MHz for the scan manager	Peripheral PLL C4	Clock for L4 SPI master bus and scan manager
emac0_clk	Up to 250 MHz	Peripheral PLL C0	EMAC0 clock. The 250 MHz clock is divided internally by the EMAC into the typical 125/25/2.5 MHz speeds for 1000/100/10 Mbps operation.

System Clock Name	Frequency	Divided From	Constraints and Notes
emac1_clk	Up to 250 MHz	Peripheral PLL C1	EMAC1 clock The 250 MHz clock is divided internally by the EMAC into the typical 125/25/2.5 MHz speeds for 1000/100/10 Mbps operation.
l4_mp_clk	Up to 100 MHz	Main PLL C1 or peripheral PLL C4	Clock for L4 master peripheral bus
l4_sp_clk	Up to 100 MHz	Main PLL C1 or peripheral PLL C4	Clock for L4 slave peripheral bus
can0_clk	Up to 100 MHz	Peripheral PLL C4	Controller area network (CAN) controller 0 clock
can1_clk	Up to 100 MHz	Peripheral PLL C4	CAN controller 1 clock
gpio_db_clk	Up to 1 MHz	Peripheral PLL C4	Used to debounce GPIO0, GPIO1, and GPIO2
h2f_user1_clock	Peripheral PLL C5	Peripheral PLL C5	Auxiliary user clock to the FPGA fabric

Flash Controller Clocks

Flash memory peripherals can be driven by the main PLL, the peripheral PLL, or from clocks provided by the FPGA fabric.

Figure 3-5: Flash Peripheral Clock Divide and Gating

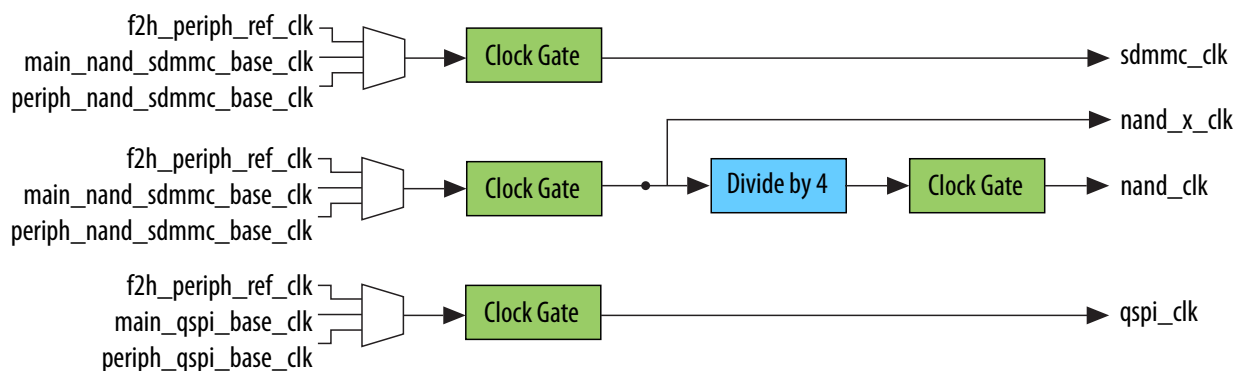

Table 3-9: Flash Controller Clocks

System Clock Name	Frequency	Divided From	Constraints and Notes
qspi_clk	Up to 432 MHz	Peripheral PLL C2, main PLL C3, or f2h_periph_ref_clk	Clock for quad SPI, typically 108 and 80 MHz
nand_x_clk	Up to 250 MHz	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	NAND flash controller master and slave clock
nand_clk	nand_x_clk/4	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	Main clock for NAND flash controller, sets base frequency for NAND transactions
sdmmc_clk	Up to 200 MHz	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	<ul style="list-style-type: none"> • Less than or equal to memory maximum operating frequency • 45% to 55% duty cycle • Typical frequencies are 25 and 50 MHz • SD/MMC has a subclock tree divided down from this clock

SDRAM Clock Group

The SDRAM clock group consists of a PLL and clock gating. The clocks in the SDRAM clock group are derived from the SDRAM PLL. The SDRAM PLL can be programmed to be sourced from the HPS_CLK1 pin, the HPS_CLK2 pin, or the f2h_sdram_ref_clk clock provided by the FPGA fabric.

The FPGA fabric must be configured with an image that provides the f2h_sdram_ref_clk before selecting it as the clock source. If the FPGA must be reconfigured and the f2h_sdram_ref_clk is the clock source for the SDRAM clock group, an alternate clock source must be selected prior to reconfiguring the FPGA.

The counter outputs from the SDRAM PLL can be gated off directly under software control. The divider values for each clock are set by registers in the clock manager.

Table 3-10: SDRAM PLL Output Assignments

PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
SDRAM	C0	ddr_dqs_base_clk	Varies (9)	Yes
	C1	ddr_2x_dqs_base_clk	ddr_dqs_base_clk x 2	Yes
	C2	ddr_dq_base_clk	ddr_dqs_base_clk	Yes
	C5	h2f_user2_base_clk	osc1_clk to varies ⁽⁹⁾	Yes

The following figure shows clock gating for SDRAM PLL clock group. Clock gate blocks in the diagram indicate clocks which may be gated off under software control. Software is expected to gate these clocks off prior to changing any PLL or divider settings that might create incorrect behavior on these clocks.

Figure 3-6: SDRAM Clock Group Divide and Gating

The SDRAM PLL output clocks can be phase shifted in real time in increments of 1/8 the VCO frequency. Maximum number of phase shift increments is 4096.

Table 3-11: SDRAM Clock Group Clocks

Name	Frequency	Constraints and Notes
ddr_dqs_clk	SDRAM PLL C0	Clock for MPFE, single-port controller, CSR access, and PHY

⁽⁹⁾ The maximum frequency depends on the speed grade of the device.

Name	Frequency	Constraints and Notes
ddr_2x_dqs_clk	SDRAM PLL C1	Clock for PHY
ddr_dq_clk	SDRAM PLL C2	Clock for PHY
h2f_user2_clock	SDRAM PLL C5	Auxiliary user clock to the FPGA fabric

Resets

Cold Reset

Cold reset places the hardware-managed clocks into safe mode, the software-managed clocks into their default state, and asynchronously resets all registers in the clock manager.

Related Information

[Safe Mode](#) on page 3-17

Warm Reset

Registers in the clock manager control how the clock manager responds to warm reset. Typically, software places the clock manager into a safe state in order to generate a known set of clocks for the ROM code to boot the system. The behavior of the system on warm reset as a whole, including how the FPGA fabric, boot code, and debug systems are configured to behave, must be carefully considered when choosing how the clock manager responds to warm reset.

The reset manager can request that the clock manager go into safe mode as part of the reset manager's warm reset sequence. Before asserting safe mode to the clock manager, the reset manager ensures that the reset signal is asserted to all modules that receive warm reset.

Related Information

[Reset Manager](#) on page 4-1

For more information, refer to "Reset Sequencing" in the *Reset Manager* chapter.

Safe Mode

Safe mode is enabled in the HPS by a cold reset. Also, if the `ensfmdwr` bit in the `ctrl` register is set, clock manager will respond to the Safe Mode request from Reset Manager on a warm reset and sets the Safe Mode bit. No other control register bits are affected by the safe mode request from the Reset Manager.

Note: By default the preloader generated by the SoC EDS tool sets the `ensfmdwr` bit after bringing the clocks out from reset. In order to ensure the stability of the system, Intel recommends that you do not clear the `ensfmdwr` bit during any of the later HPS boot stages.

When safe mode is enabled, the main PLL hardware-managed clocks (C0-C2) are bypassed to `osc1_clk` clock and are directly generated from `osc1_clk`. While in safe mode, clock manager register settings, which control clock behavior, are not changed. However, the hardware bypasses these settings and uses safe, default settings.

The hardware-managed clocks are forced to their safe mode values such that the following conditions occur:

- The hardware-managed clocks are bypassed to `oscl_clk`, including counters in the main PLL.
- Programmable dividers select the reset default values.
- The flash controller clocks multiplexer selects the output from the peripheral PLL.
- All clocks are enabled.

A write by software is the only way to clear the safe mode bit (`safemode`) of the `ctrl` register.

Note: Before coming out of safe mode, all registers and clocks must be configured correctly. It is possible to program the clock manager in such a way that only a cold reset can return the clocks to a functioning state. Intel strongly recommends using provided libraries to configure and control HPS clocks.

Interrupts

The clock manager provides one interrupt output which is enabled using the interrupt enable register (`intren`). The interrupt is the OR of the bits in the interrupt status register (`inter`) that indicate lock and loss of lock for each of the three PLLs.

Clock Usage By Module

The following table lists every clock input generated by the clock manager to all modules in the HPS. System clock names are global for the entire HPS and system clocks with the same name are phase-aligned at all endpoints.

Table 3-12: Clock Usage By Module

Module Name	System Clock Name	Use
MPU subsystem	<code>mpu_clk</code>	Main clock for the MPU subsystem
	<code>mpu_periph_clk</code>	Peripherals inside the MPU subsystem
	<code>dbg_at_clk</code>	Trace bus
	<code>dbg_clk</code>	Debug
	<code>mpu_l2_ram_clk</code>	L2 cache and Accelerator Coherency Port (ACP) ID mapper
	<code>l4_mp_clk</code>	ACP ID mapper control slave

Module Name	System Clock Name	Use
Interconnect	13_main_clk	L3 main switch
	dbg_at_clk	System Trace Macrocell (STM) slave and Embedded Trace Router (ETR) master connections
	dbg_clk	DAP master connection
	13_mp_clk	L3 master peripheral switch
	14_mp_clk	L4 MP bus, Secure Digital (SD) / MultiMediaCard (MMC) master, and EMAC masters
	usb_mp_clk	USB masters and slaves
	nand_x_clk	NAND master
	cfg_clk	FPGA manager configuration data slave
	13_sp_clk	L3 slave peripheral switch
	13_main_clk	L4 SPIS bus master
	mpu_l2_ram_clk	ACP ID mapper slave and L2 master connections
	osc1_clk	L4 OSC1 bus master
	spi_m_clk	L4 SPIM bus master
	14_sp_clk	L4 SP bus master
	14_mp_clk	Quad SPI bus slave
Boot ROM	13_main_clk	Boot ROM
On-chip RAM	13_main_clk	On-chip RAM

Module Name	System Clock Name	Use
DMA controller	14_main_clk	DMA
	dbg_at_clk	Synchronous to the STM module
	14_mp_clk	Synchronous to the quad SPI flash
FPGA manager	cfg_clk	Control block (CB) data interface and configuration data slave
	14_mp_clk	Control slave
HPS-to-FPGA bridge	13_main_clk	Data slave
	14_mp_clk	Global programmer's view (GPV) slave
FPGA-to-HPS bridge	13_main_clk	Data master
	14_mp_clk	GPV slave
Lightweight HPS-to-FPGA bridge	14_mp_clk	GPV masters and the data and GPV slave
Quad SPI flash controller	14_mp_clk	Control slave
	qspi_clk	Reference for serialization
SD/MMC controller	14_mp_clk	Master and slave
	sdmmc_clk	SD/MMC internal logic
EMAC 0	14_mp_clk	Master
	emac0_clk	EMAC 0 internal logic
	osc1_clk	IEEE 1588 timestamp

Module Name	System Clock Name	Use
EMAC 1	14_mp_clk	Master
	emac1_clk	EMAC 1 internal logic
	osc1_clk	IEEE 1588 timestamp
USB 0	usb_mp_clk	Master and Slave
USB 1	usb_mp_clk	Master and Slave
NAND flash controller	nand_x_clk	NAND high-speed master and slave
	nand_clk	NAND flash
OSC1 timer 0	osc1_clk	OSC1 timer 0
OSC1 timer 1	osc1_clk	OSC1 timer 1
SP timer 0	14_sp_clk	SP timer 0
SP timer 1	14_sp_clk	SP timer 1
I ² C controller 0	14_sp_clk	I ² C 0
I ² C controller 1	14_sp_clk	I ² C 1
I ² C controller 2	14_sp_clk	I ² C 2
I ² C controller 3	14_sp_clk	I ² C 3
UART controller 0	14_sp_clk	UART 0
UART controller 1	14_sp_clk	UART 1

Module Name	System Clock Name	Use
CAN controller 0	14_sp_clk	Slave
	can0_clk	CAN 0 controller
CAN controller 1	14_sp_clk	Slave
	can1_clk	CAN 1 controller
GPIO interface 0	14_mp_clk	Slave
	gpio_db_clk	Debounce
GPIO interface 1	14_mp_clk	Slave
	gpio_db_clk	Debounce
GPIO interface 2	14_mp_clk	Slave
	gpio_db_clk	Debounce
System manager	osc1_clk	System manager
SDRAM subsystem	14_sp_clk	Control slave
	ddr_dq_clk	Off-chip data
	ddr_dqs_clk	MPFE, single-port controller, CSRs, and PHY
	ddr_2x_dqs_clk	Off-chip strobe data
	mpu_12_ram_clk	Slave connected to MPU subsystem L2 cache
	13_main_clk	Slave connected to L3 interconnect
L4 watchdog timer 0	osc1_clk	L4 watchdog timer 0

Module Name	System Clock Name	Use
L4 watchdog timer 1	oscl_clk	L4 watchdog timer 1
SPI master controller 0	spi_m_clk	SPI master 0
SPI master controller 1	spi_m_clk	SPI master 1
SPI slave controller 0	l4_main_clk	SPI slave 0
SPI slave controller 1	l4_main_clk	SPI slave 1
Debug subsystem	l4_mp_clk	System bus
	dbg_clk	Debug
	dbg_at_clk	Trace bus
	dbg_trace_clk	Trace port
Reset manager	oscl_clk	Reset manager
	l4_sp_clk	Slave
Scan manager	spi_m_clk	Scan manager
Timestamp generator	dbg_timer_clk	Timestamp generator

Clock Manager Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- Clock Manager Module

Related Information

- [Introduction to the Hard Processor System](#) on page 2-1
The base addresses of all modules are also listed in the *Introduction to the Hard Processor System* chapter.

dbctrl Fields

Bit	Name	Description	Access	Reset
1	ensfmdwr	When this bit is set the debug clocks will be affected by the assertion of Safe Mode on a warm reset if Stay OSC1 is not set. When this bit is clear the debug clocks will not be affected by the assertion of Safe Mode on a warm reset. If Debug Clocks are in Safe Mode they are taken out of Safe Mode when the Safe Mode bit is cleared independent of this bit. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x1
0	stayosc1	When this bit is set the debug root clock (Main PLL C2 output) will always be bypassed to the EOSC1_clk independent of any other clock manager settings. When clear the debug source will be a function of register settings in the clock manager. Clocks affected by this bit are dbg_at_clk, dbg_clk, dbg_trace_clk, and dbg_timer_clk. The reset value for this bit is applied on a cold reset. Warm reset has no effect on this bit.	RW	0x1

stat

Provides status of Hardware Managed Clock transition State Machine.

Module Instance	Base Address	Register Address
clkmgr	0xFFD04000	0xFFD04014

Main PLL Group Register Descriptions

Contains registers with settings for the Main PLL.

Offset: 0x40

[vco](#) on page 3-35

Contains settings that control the Main PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). The VCO input clock source is always eoscl_clk. Fields are only reset by a cold reset.

[misc](#) on page 3-37

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

[mpuclk](#) on page 3-38

Contains settings that control clock mpu_clk generated from the C0 output of the Main PLL. Only reset by a cold reset.

[mainclk](#) on page 3-39

Contains settings that control clock main_clk generated from the C1 output of the Main PLL. Only reset by a cold reset.

[dbgatclk](#) on page 3-40

Contains settings that control clock dbg_base_clk generated from the C2 output of the Main PLL. Only reset by a cold reset.

[mainqspiclk](#) on page 3-40

Contains settings that control clock main_qspi_clk generated from the C3 output of the Main PLL. Only reset by a cold reset.

mainnandsdmmclk on page 3-41

Contains settings that control clock main_nand_sdmmc_clk generated from the C4 output of the Main PLL. Only reset by a cold reset.

cfgs2fuser0clk on page 3-42

Contains settings that control clock cfg_s2f_user0_clk generated from the C5 output of the Main PLL. Platform Designer (Standard) and user documentation refer to cfg_s2f_user0_clk as cfg_h2f_user0_clk. Only reset by a cold reset.

en on page 3-42

Contains fields that control clock enables for clocks derived from the Main PLL. 1: The clock is enabled. 0: The clock is disabled. Fields are only reset by a cold reset.

maindiv on page 3-43

Contains fields that control clock dividers for main clocks derived from the Main PLL Fields are only reset by a cold reset.

dbgdiv on page 3-45

Contains fields that control clock dividers for debug clocks derived from the Main PLL Fields are only reset by a cold reset.

tracediv on page 3-46

Contains a field that controls the clock divider for the debug trace clock derived from the Main PLL Only reset by a cold reset.

l4src on page 3-47

Contains fields that select the clock source for L4 MP and SP APB interconnect Fields are only reset by a cold reset.

stat on page 3-48

Contains Output Clock Counter Reset acknowledge status.

vco

Contains settings that control the Main PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). The VCO input clock source is always eoscl1_clk. Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
clkmgr	0xFFD04000	0xFFD04040

Offset: 0x40

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

numer RW 0x1												pwrn RW 0x1	en RW 0x0	bgpwrn RW 0x1		

vco Fields

Bit	Name	Description	Access	Reset
31	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is selected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulator once the PLL becomes enabled. Software should simultaneously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x1
30:25	oureset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. LSB 'oureset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x0

Bit	Name	Description	Access	Reset
24	ouresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0
21:16	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
15:3	numer	Numerator in VCO output frequency equation. Note that the valid range for this field is 0x000 to 0xFFFF (0 to 4095). The most significant bit of this field is reserved and should not be used. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
2	pwrdsn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
1	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
0	bgpwrdsn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

misc

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
clkmgr	0xFFD04000	0xFFD04044

Offset: 0x44

Peripheral PLL Group Register Descriptions

Contains registers with settings for the Peripheral PLL.

Offset: 0x80

vco on page 3-50

Contains settings that control the Peripheral PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

misc on page 3-52

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

emac0clk on page 3-53

Contains settings that control clock emac0_clk generated from the C0 output of the Peripheral PLL. Only reset by a cold reset.

emac1clk on page 3-54

Contains settings that control clock emac1_clk generated from the C1 output of the Peripheral PLL. Only reset by a cold reset.

perqspick on page 3-54

Contains settings that control clock periph_qspi_clk generated from the C2 output of the Peripheral PLL. Only reset by a cold reset.

pernandsdmmcclk on page 3-55

Contains settings that control clock periph_nand_sdmmc_clk generated from the C3 output of the Peripheral PLL. Only reset by a cold reset.

perbaseclk on page 3-56

Contains settings that control clock `periph_base_clk` generated from the C4 output of the Peripheral PLL. Only reset by a cold reset.

s2fuser1clk on page 3-56

Contains settings that control clock `s2f_user1_clk` generated from the C5 output of the Peripheral PLL. Platform Designer (Standard) and user documentation refer to `s2f_user1_clk` as `h2f_user1_clk`. Only reset by a cold reset.

en on page 3-57

Contains fields that control clock enables for clocks derived from the Peripheral PLL 1: The clock is enabled. 0: The clock is disabled. Fields are only reset by a cold reset.

div on page 3-58

Contains fields that control clock dividers for clocks derived from the Peripheral PLL Fields are only reset by a cold reset.

gpiodiv on page 3-61

Contains a field that controls the clock divider for the GPIO De-bounce clock. Only reset by a cold reset.

src on page 3-62

Contains fields that select the source clocks for the flash controllers. Fields are only reset by a cold reset.

stat on page 3-63

Contains Output Clock Counter Reset acknowledge status.

VCO

Contains settings that control the Peripheral PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

vco Fields

Bit	Name	Description	Access	Reset								
31	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is selected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulator once the PLL becomes enabled. Software should simultaneously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x1								
30:25	oureset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. LSB 'oureset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x0								
24	ouresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0								
23:22	psrc	Controls the VCO input clock source. Platform Designer (Standard) and user documentation refer to f2s_periph_ref_clk as f2h_periph_ref_clk. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>eosc1_clk</td> </tr> <tr> <td>0x1</td> <td>eosc2_clk</td> </tr> <tr> <td>0x2</td> <td>f2s_periph_ref_clk</td> </tr> </tbody> </table>	Value	Description	0x0	eosc1_clk	0x1	eosc2_clk	0x2	f2s_periph_ref_clk	RW	0x0

SDRAM PLL Group Register Descriptions

Contains registers with settings for the SDRAM PLL.

Offset: 0xc0

[vco](#) on page 3-65

Contains settings that control the SDRAM PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

[ctrl](#) on page 3-67

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

[ddrdqsclk](#) on page 3-68

Contains settings that control clock ddr_dqs_clk generated from the C0 output of the SDRAM PLL. Fields are only reset by a cold reset.

[ddr2xdqsclk](#) on page 3-69

Contains settings that control clock ddr_2x_dqs_clk generated from the C1 output of the SDRAM PLL. Fields are only reset by a cold reset.

[ddrdqclk](#) on page 3-70

Contains settings that control clock ddr_dq_clk generated from the C2 output of the SDRAM PLL. Fields are only reset by a cold reset.

s2fuser2clk on page 3-71

Contains settings that control clock s2f_user2_clk generated from the C5 output of the SDRAM PLL. Platform Designer (Standard) and user documentation refer to s2f_user2_clk as h2f_user2_clk Fields are only reset by a cold reset.

en on page 3-72

Contains fields that control the SDRAM Clock Group enables generated from the SDRAM PLL clock outputs. 1: The clock is enabled. 0: The clock is disabled. Fields are only reset by a cold reset.

stat on page 3-73

Contains Output Clock Counter Reset acknowledge status.

vco

Contains settings that control the SDRAM PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

vco Fields

Bit	Name	Description	Access	Reset								
31	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is selected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulator once the PLL becomes enabled. Software should simultaneously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x1								
30:25	oureset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. LSB 'oureset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x0								
24	ouresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0								
23:22	ssrc	Controls the VCO input clock source. The PLL must be bypassed to eosc1_clk before changing this field. Platform Designer (Standard) and user documentation refer to f2s_sdram_ref_clk as f2h_sdram_ref_clk. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>eosc1_clk</td> </tr> <tr> <td>0x1</td> <td>eosc2_clk</td> </tr> <tr> <td>0x2</td> <td>f2s_sdram_ref_clk</td> </tr> </tbody> </table>	Value	Description	0x0	eosc1_clk	0x1	eosc2_clk	0x2	f2s_sdram_ref_clk	RW	0x0
Value	Description											
0x0	eosc1_clk											
0x1	eosc2_clk											
0x2	f2s_sdram_ref_clk											

Bit	Name	Description	Access	Reset
21:16	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
15:3	numer	Numerator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
2	pwrdsn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
1	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
0	bgpwrdsn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

ctrl

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address

The reset manager generates module reset signals based on reset requests from the various sources in the HPS and FPGA fabric, and software writing to the module-reset control registers. The reset manager ensures that a reset request from the FPGA fabric can occur only after the FPGA portion of the system-on-a-chip (SoC) device is configured.

The HPS contains multiple reset domains. Each reset domain can be reset independently. A reset may be initiated externally, internally or through software.

Table 4-1: HPS Reset Domains

Domain Name	Domain Logic
TAP	JTAG test access port (TAP) controller, which is used by the debug access port (DAP).
Debug	All debug logic including most of the DAP, CoreSight™ components connected to the debug peripheral bus, trace, the microprocessor unit (MPU) subsystem, and the FPGA fabric.
System	All HPS logic except what is in the TAP and debug reset domains. Includes non-debug logic in the FPGA fabric connected to the HPS reset signals.

The HPS supports the following reset types:

- System cold reset
 - Used to ensure the HPS is placed in a default state sufficient for software to boot
 - Triggered by a power-on reset and other sources
 - Resets all HPS logic that can be reset
 - Affects all reset domains
- System warm reset
 - Occurs after HPS has already completed a cold reset
 - Used to recover system from a non-responsive condition
 - Resets a subset of the HPS state reset by a cold reset
 - Only affects the system reset domain, which allows debugging (including trace) to operate through the warm reset
- Debug reset
 - Used to recover debug logic from a non-responsive condition
 - Only affects the debug reset domain

Reset Manager Block Diagram and System Integration

The following figure shows a block diagram of the reset manager in the SoC device. For clarity, reset-related handshaking signals to other HPS modules and to the clock manager module are omitted.

Figure 4-1: Reset Manager Block Diagram

HPS External Reset Sources

The following table lists the reset sources external to the HPS. All signals are synchronous to the `osc1_clk` clock. The reset signals from the HPS to the FPGA fabric must be synchronized to your user logic clock domain.

Table 4-2: HPS External Reset Sources

Source	Description
f2h_cold_rst_req_n	Cold reset request from FPGA fabric (active low)
f2h_warm_rst_req_n	Warm reset request from FPGA fabric (active low)
f2h_dbg_rst_req_n	Debug reset request from FPGA fabric (active low)
h2f_cold_rst_n	Cold-only reset to FPGA fabric (active low)
h2f_rst_n	Cold or warm reset to FPGA fabric (active low)
h2f_dbg_rst_n	Debug reset (dbg_rst_n) to FPGA fabric (active low)
load_csr	Cold-only reset from FPGA control block (CB) and scan manager
nPOR	Power-on reset pin (active low)
nRST	Warm reset pin (active low)

nRST and nPOR are powered by the HPS reset and clock input pins power supply ($V_{CCRSTCLK_HPS}$). For more information on $V_{CCRSTCLK_HPS}$, refer to the *Cyclone V Device Datasheet*.

Related Information

[Cyclone V Device Datasheet](#)

For information about the required duration of reset request signal assertion, refer to the *Cyclone V Device Datasheet*.

Reset Controller

The reset controller performs the following functions:

- Accepts reset requests from the FPGA CB, FPGA fabric, modules in the HPS, and reset pins
- Generates an individual reset signal for each module instance for all modules in the HPS
- Provides reset handshaking signals to support system reset behavior

The reset controller generates module reset signals from external reset requests and internal reset requests. External reset requests originate from sources external to the reset manager. Internal reset requests originate from control registers in the reset manager.

The reset controller supports the following cold reset requests:

- Power-on reset (POR) voltage monitor
- Cold reset request pin (nPOR)
- FPGA fabric
- FPGA CB and scan manager
- Software cold reset request bit (`swcoldrstreq`) of the control register (`ctrl1`)

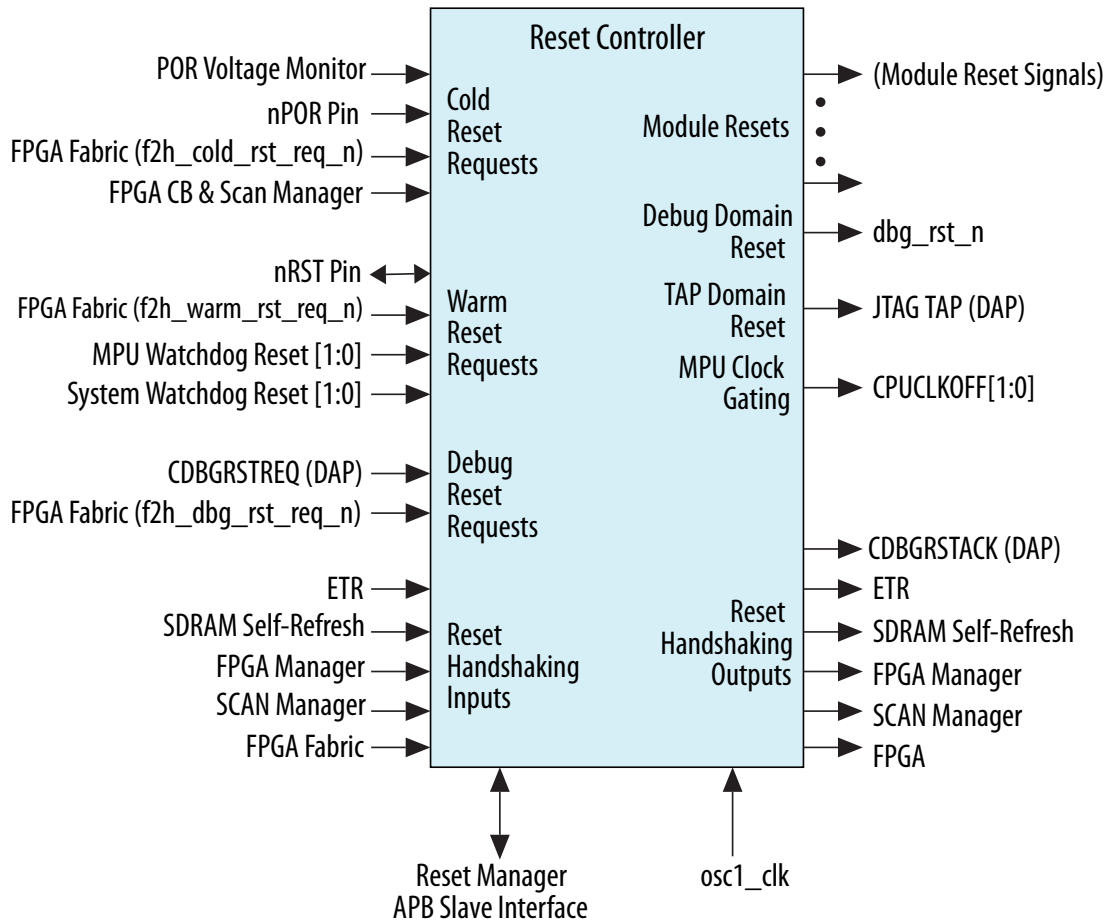

The reset controller supports the following warm reset requests:

- Warm reset request pin ($nRST$)
- FPGA fabric
- Software warm reset request bit ($swwarmrstreq$) of the `ctrl` register
- MPU watchdog reset requests for CPU0 and CPU1
- System watchdog timer 0 and 1 reset requests

The reset controller supports the following debug reset requests:

- CDBGIRSTREQ from DAP
- FPGA fabric

Figure 4-2: Reset Controller Signals

Module Reset Signals

The following tables list the module reset signals. The module reset signals are organized in groups for the MPU, peripherals, bridges.

In the following tables, columns marked for Cold Reset, Warm Reset, and Debug Reset denote reset signals asserted by each type of reset. For example, writing a 1 to the $swwarmrstreq$ bit in the `ctrl` register resets all the modules that have a checkmark in the Warm Reset column.

The column marked for Software Deassert denotes reset signals that are left asserted by the reset manager.

Table 4-3: MPU Group, Generated Module Resets

Module Reset Signal	Description	Reset Domain	Cold Reset	Warm Reset	Debug Reset	Software Deassert
mpu_cpu_rst_n[0]	Resets each processor in the MPU	System	X	X

Modules Requiring Software Deassert

The reset manager leaves the reset signal asserted on certain modules even after the rest of the HPS has come out of reset. These modules are likely to require software configuration before they can safely be taken out of reset.

When a module that has been held in reset is ready to start running, software can deassert the reset signal by writing to the appropriate register, shown in the following table.

Table 4-9: Module Reset Signals and Registers

HPS Peripheral	Reset Register	Module Reset Signal	Reset Group

Slave Interface and Status Register

The reset manager slave interface is used to control and monitor the reset states.

The status register (*stat*) in the reset manager contains the status of the reset requester. The register contains a bit for each monitored reset request. The *stat* register captures all reset requests that have occurred. Software is responsible for clearing the bits.

During the boot process, the Boot ROM copies the *stat* register value into memory before clearing it. After booting, you can read the value of the reset status register at memory address (*r0* + 0x0038). For more information, refer to the "Shared Memory" section of the *Booting and Configuration* appendix.

Related Information

[Shared Memory](#) on page 31-31

Functional Description of the Reset Manager

The reset manager generates reset signals to modules in the HPS and to the FPGA fabric. The following actions generate reset signals:

- Software writing a 1 to the *swcoldrstreq* or *swarmrstreq* bits in the *ctrl* register. Writing either bit causes the reset controller to perform a reset sequence.
- Software writing to the *mpumodrst*, *permodrst*, *per2modrst*, *brgmodrst*, or *miscmodrst* module reset control registers.
- Asserting reset request signals triggers the reset controller. All external reset requests cause the reset controller to perform a reset sequence.

Multiple reset requests can be driven to the reset manager at the same time. Cold reset requests take priority over warm and debug reset requests. Higher priority reset requests preempt lower priority reset requests. There is no priority difference among reset requests within the same domain.

If a cold reset request is issued while another cold reset is already underway, the reset manager extends the reset period for all the module reset outputs until all cold reset requests are removed. If a cold reset request is issued while the reset manager is removing other modules out of the reset state, the reset manager returns those modules back to the reset state.

If a warm reset request is issued while another warm reset is already underway, the first warm reset completes before the second warm reset begins. If the second warm reset request is removed before the first warm reset completes, the warm first reset is extended to meet the timing requirements of the second warm reset request.

The `nPOR` pin can be used to extend the cold reset beyond what the POR voltage monitor automatically provides. The use of the `nPOR` pin is optional and can be tied high when it is not required.

Related Information

[Cyclone V Device Datasheet](#)

For information about the required duration of reset request signal assertion, refer to the Cyclone V Device Datasheet.

Reset Sequencing

The reset controller sequences resets without software assistance. Module reset signals are asserted asynchronously and synchronously. The reset manager deasserts the module reset signals synchronous to the `osc1_clk` clock. Module reset signals are deasserted in groups in a fixed sequence. All module reset signals in a group are deasserted at the same time.

The reset manager sends a safe mode request to the clock manager to put the clock manager in safe mode, which creates a fixed and known relationship between the `osc1_clk` clock and all other clocks generated by the clock manager.

After the reset manager releases the MPU subsystem from reset, CPU1 is left in reset and CPU0 begins executing code from the reset vector address. Software is responsible for deasserting CPU1 and other resets, as shown in the MPU Group and Generated Module Resets table. Software deasserts resets by writing the `mpumodrst`, `permodrst`, `per2modrst`, `brgmodrst`, and `miscmodrst` module-reset control registers.

Software can also bypass the reset controller and generate reset signals directly through the module-reset control registers. In this case, software is responsible for asserting module reset signals, driving them for the appropriate duration, and deasserting them in the correct order. The clock manager is not typically in safe mode during this time, so software is responsible for knowing the relationship between the clocks generated by the clock manager. Software must not assert a module reset signal that would prevent software from deasserting the module reset signal. For example, software should not assert the module reset to the processor executing the software.

Table 4-10: Minimum Pulse Width

Reset Type	Value
Warm Reset	6 <code>osc1_clk</code> cycles
Cold Reset	6 <code>osc1_clk</code> cycles

Figure 4-3: Cold Reset Timing Diagram

- (1) Cold reset can be initiated from several other sources: FPGA CB, FPGA fabric, modules in the HPS, and reset pins.
- (2) This dependency applies to all the reset signals.

Figure 4-4: Warm Reset Timing Diagram

(1) Cold reset can be initiated from several other sources: FPGA CB, FPGA fabric, modules in the HPS, and reset pins.

(2) When the nRSTpin count is zero, the 256 cycle stretch count is skipped and the start of the deassertion sequence is determined by the safe mode acknowledge signal or the user releasing the warm reset button, whichever occurs later.

The cold and warm reset sequences consist of different reset assertion sequences and the same deassertion sequence. The following sections describe the sequences.

Note: Cold and warm reset affect only the `cpu0`, and by default `cpu1` is held in reset until the software running in the `cpu0` releases it.

- For more information about safe mode, refer to the *Clock Manager* chapter.

Cold Reset Assertion Sequence

The following list describes the assertion steps for cold reset shown in the Cold Reset timing diagram:

1. Assert module resets
2. Wait for 32 cycles. Deassert clock manager cold reset.
3. Wait for 96 cycles (so clocks can stabilize).
4. Proceed to the “Cold and Warm Reset Deassertion Sequence” section using the following link.

Related Information

[Cold and Warm Reset Deassertion Sequence](#) on page 4-14

Warm Reset Assertion Sequence

The following list describes the assertion steps for warm reset shown in the Warm Reset Timing Diagram:

1. Optionally, handshake with the embedded trace router (ETR) and wait for acknowledge.
2. Optionally, handshake with the FPGA fabric and wait for acknowledge.
3. Optionally, handshake with the SDRAM controller, scan manager, and FPGA manager, and wait for acknowledges.
4. Assert module resets (except the MPU watchdog timer resets when the MPU watchdog timers are the only request sources).
5. Wait for 8 cycles and send a safe mode request to the clock manager.
6. Wait for the greater of the nRST pin count + 256 stretch count, or the warm reset counter, or the clock manager safe mode acknowledge, then deassert all handshakes except warm reset ETR handshake (which is deasserted by software).
7. Proceed to the “Cold and Warm Reset Deassertion Sequence” section using the following link.

Note: The nRST is a bidirectional signal that is driven out when a warm reset is generated in the chip.

Related Information

[Cold and Warm Reset Deassertion Sequence](#) on page 4-14

Cold and Warm Reset Deassertion Sequence

The following list describes the deassertion steps for both cold and warm reset shown in the Cold Reset Timing Diagram and Warm Reset Timing Diagram:

1. Deassert L3 reset.
2. Wait for 100 cycles. Deassert resets for miscellaneous-type and debug (cold only) modules.
3. Wait for 200 cycles. Assert `mpu_clkoff` for CPU0 and CPU1.
4. Wait for 32 cycles. Deassert resets for MPU modules.
5. Wait for 32 cycles. Deassert `mpu_clkoff` for CPU0 and CPU1.
6. Peripherals remain held in reset until software brings them out of reset.

Reset Pins

Figure 4-5: Reset Pins

The test reset ($nTRST$), test mode select (TMS), and test clock (TCK) pins are associated with the TAP reset domain and are used to reset the TAP controller in the DAP. These pins are not connected to the reset manager.

The $nPOR$ and $nRST$ pins are used to request cold and warm resets respectively. The $nRST$ pin is an open drain output as well. A warm reset drives the $nRST$ pin low. The amount of time the reset manager pulls $nRST$ low is controlled by the $nRST$ pin count field ($nrstcnt$) of the reset cycles count register ($counts$). This technique can be used to reset external devices (such as external memories) connected to the HPS.

Reset Effects

The following list describes how reset affects HPS logic:

- The TAP reset domain ignores warm reset.
- The debug reset domain ignores warm reset.
- System reset domain cold resets ignore warm reset.
- Each module defines reset behavior individually.

Altering Warm Reset System Response

Registers in the clock manager, system manager, and reset manager control how warm reset affects the HPS. You can control the impact of a warm reset on the clocks and I/O elements.

Intel strongly recommends using provided libraries to configure and control this functionality.

The default warm reset behavior takes all clocks and I/O elements through a cold reset response. As your software becomes more stable or for debug purposes, you can alter the system response to a warm reset. The following suggestions provide ways to alter the system response to a warm reset. None of the register bits that control these items are affected by warm reset.

- Boot from on-chip RAM—enables warm boot from on-chip RAM instead of the boot ROM. When enabled, the boot ROM code validates the RAM code and jumps to it, making no changes to clocks or any other system settings prior to executing user code from on-chip RAM.
- Disable safe mode on warm reset—allows software to transition through a warm reset without affecting the clocks. Because the boot ROM code indirectly configures the clock settings after warm reset, Intel recommends that safe mode should only be disabled when the HPS is not booting from a flash device.
- Disable safe mode on warm reset for the debug clocks—keeps the debug clocks from being affected by the assertion of safe mode request on a warm reset. This technique allows fast debug clocks, such as trace, to continue running through a warm reset. When enabled, the clock manager configures the debug clocks to their safe frequencies to respond to a safe mode request from the reset manager on a warm reset. Disable safe mode on warm reset for the debug clocks only when you are running the debug clocks off the main PLL VCO and you are certain the main PLL cannot be impacted by the event which caused the warm reset.
- Use the `osc1_clk` clock for debug control—keeps the debug base clock (main PLL C2 output) always bypassed to the `osc1_clk` external clock, independent of other clock manager settings. When implemented, disabling safe mode on warm reset for the debug clocks has no effect.

Related Information

[Clock Manager](#) on page 3-1

For more information about safe mode, refer to the *Clock Manager* chapter.

Reset Handshaking

The reset manager participates in several reset handshaking protocols to ensure other modules are safely reset.

Before issuing a warm reset, the reset manager performs a handshake with several modules to allow them to prepare for a warm reset. The handshake logic ensures the following conditions:

- Optionally the ETR master has no pending master transactions to the L3 interconnect
- Optionally preserve SDRAM contents during warm reset by issuing self-refresh mode request
- FPGA manager stops generating configuration clock
- Scan manager stops generating JTAG and I/O configuration clocks
- Warns the FPGA fabric of the forthcoming warm reset

Similarly, the handshake logic associated with ETR also occurs during the debug reset to ensure that the ETR master has no pending master transactions to the L3 interconnect before the debug reset is issued. This action ensures that when ETR undergoes a debug reset, the reset has no adverse effects on the system domain portion of the ETR.

Reset Manager Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- Reset Manager Module

Reset Manager Module Address Map

Registers in the Reset Manager module

Base Address: 0xFFD05000

stat

The STAT register contains bits that indicate the reset source or a timeout event. For reset sources, a field is 1 if its associated reset requester caused the reset. For timeout events, a field is 1 if its associated timeout occurred as part of a hardware sequenced warm/debug reset. Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored. After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0. After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any of the bits in the STAT register; these bits must be cleared by software writing the STAT register. During the boot process, the Boot ROM copies the STAT register value into memory before clearing it. After booting, you can read the value of the reset status register at memory address ($r0 + 0x0038$).

ctrl

The CTRL register is used by software to control reset behavior. It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform software handshake. The software handshake sequence must match the hardware sequence. Software must de-assert the handshake request after asserting warm reset and before de-assert the warm reset. Fields are only reset by a cold reset.

ctrl Fields

Bit	Name	Description	Access	Reset
23	etrstallwarmrst	If a warm reset occurs and ETRSTALLEN is 1, hardware sets this bit to 1 to indicate that the stall of the ETR AXI master is pending. Hardware leaves the ETR stalled until software clears this field by writing it with 1. Software must only clear this field when it is ready to have the ETR AXI master start making AXI requests to write trace data.	RW	0x0
22	etrstallack	This is the acknowledge for a ETR AXI master stall initiated by the ETRSTALLREQ field. A 1 indicates that the ETR has stalled its AXI master	RO	0x0
21	etrstallreq	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0

Bit	Name	Description	Access	Reset
20	etrstallen	This field controls whether the ETR is requested to idle its AXI master interface (i.e. finish outstanding transactions and not initiate any more) to the L3 Interconnect before a warm or debug reset. If set to 1, the Reset Manager makes a request to the ETR to stall its AXI master and waits for it to finish any outstanding AXI transactions before a warm reset of the L3 Interconnect or a debug reset of the ETR. This stalling is required because the debug logic (including the ETR) is reset on a debug reset and the ETR AXI master is connected to the L3 Interconnect which is reset on a warm reset and these resets can happen independently.	RW	0x1
18	fpgahsack	This is the acknowledge (high active) that the FPGA handshake acknowledge has been received by Reset Manager.	RO	0x0
17	fpgahsreq	Software writes this field 1 to initiate handshake request to FPGA . Software waits for the FPGAHSACK to be active and then writes this field to 0. Note that it is possible for the FPGA to never assert FPGAHSACK so software should timeout in this case.	RW	0x0
16	fpgahsen	This field controls whether to perform handshake with FPGA before asserting warm reset. If set to 1, the Reset Manager makes a request to the FPGA before asserting warm reset signals. However if FPGA is already in warm reset state, the handshake is not performed. If set to 0, the handshake is not performed	RW	0x0
14	scanmgrhsack	This is the acknowledge (high active) that the SCAN manager has successfully idled its output clocks.	RO	0x0
13	scanmgrhsreq	Software writes this field 1 to request to the SCAN manager to idle its output clocks. Software waits for the SCANMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the Scan Manager to never assert SCANMGRHSACK (e.g. its input clock is disabled) so software should timeout in this case.	RW	0x0

Bit	Name	Description	Access	Reset
12	scanmgrhsen	Enables a handshake between the Reset Manager and Scan Manager before a warm reset. The handshake is used to warn the Scan Manager that a warm reset is coming so it can prepare for it. When the Scan Manager receives a warm reset handshake, the Scan Manager drives its output clocks to a quiescent state to avoid glitches. If set to 1, the Reset Manager makes a request to the Scan Manager before asserting warm reset signals. However if the Scan Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0
10	fpgamgrhsack	This is the acknowledge (high active) that the FPGA manager has successfully idled its output clock.	RO	0x0
9	fpgamgrhsreq	Software writes this field 1 to request to the FPGA Manager to idle its output clock. Software waits for the FPGAMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the FPGA Manager to never assert FPGAMGRHSACK so software should timeout in this case.	RW	0x0
8	fpgamgrhsen	Enables a handshake between the Reset Manager and FPGA Manager before a warm reset. The handshake is used to warn the FPGA Manager that a warm reset is coming so it can prepare for it. When the FPGA Manager receives a warm reset handshake, the FPGA Manager drives its output clock to a quiescent state to avoid glitches. If set to 1, the Manager makes a request to the FPGA Manager before asserting warm reset signals. However if the FPGA Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0
6	sdrselfreqack	This is the acknowledge for a SDRAM self-refresh mode request initiated by the SDRSELFREFREQ field. A 1 indicates that the SDRAM Controller Subsystem has put the SDRAM devices into self-refresh mode.	RO	0x0
5	sdrselfrefreq	Software writes this field 1 to request to the SDRAM Controller Subsystem that it puts the SDRAM devices into self-refresh mode. This is done to preserve SDRAM contents across a software warm reset. Software waits for the SDRSELFREFACK to be 1 and then writes this field to 0. Note that it is possible for the SDRAM Controller Subsystem to never assert SDRSELFREFACK so software should timeout if SDRSELFREFACK is never asserted.	RW	0x0

Bit	Name	Description	Access	Reset
4	sdrselfrefen	This field controls whether the contents of SDRAM devices survive a hardware sequenced warm reset. If set to 1, the Reset Manager makes a request to the SDRAM Controller Subsystem to put the SDRAM devices into self-refresh mode before asserting warm reset signals. However, if SDRAM is already in warm reset, Handshake with SDRAM is not performed.	RW	0x0
1	swwarmrstreq	This is a one-shot bit written by software to 1 to trigger a hardware sequenced warm reset. It always reads the value 0.	RW	0x0
0	swcoldrstreq	This is a one-shot bit written by software to 1 to trigger a cold reset. It always reads the value 0.	RW	0x0

counts

The COUNTS register is used by software to control reset behavior. It includes fields for software to control the behavior of the warm reset and nRST pin. Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
rstmgr	0xFFD05000	0xFFD05008

Offset: 0x8

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

counts Fields

Bit	Name	Description	Access	Reset
27:8	nrstcnt	The Reset Manager pulls down the nRST pin on a cold or warm reset for the number of cycles specified in this register. A value of 0x0 prevents the Reset Manager from pulling down the nRST pin.	RW	0x800
7:0	warmrstcycles	On a warm reset, the Reset Manager releases the reset to the Clock Manager, and then waits for the number of cycles specified in this register before releasing the rest of the hardware controlled resets. Value must be greater than 16.	RW	0x80

mpumodrst

The MPUMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software. Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal. All fields except CPU1 are only reset by a cold reset. The CPU1 field is reset by a cold or warm reset.

Module Instance	Base Address	Register Address
rstmgr	0xFFD05000	0xFFD05010

Offset: 0x10

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

mpumodrst Fields

Bit	Name	Description	Access	Reset
4	l2	Resets L2 cache controller	RW	0x0
3	scuper	Resets SCU and peripherals. Peripherals consist of the interrupt controller, global timer, both per-CPU private timers, and both per-CPU watchdogs (except for the Watchdog Reset Status registers).	RW	0x0
2	wds	Resets both per-CPU Watchdog Reset Status registers in MPU.	RW	0x0
1	cpu1	Resets Cortex-A9 CPU1 in MPU. It is reset to 1 on a cold or warm reset. This holds CPU1 in reset until software is ready to release CPU1 from reset by writing 0 to this field. On single-core devices, writes to this field are ignored. On dual-core devices, writes to this field trigger the same sequence as writes to the CPU0 field (except the sequence is performed on CPU1).	RW	0x1
0	cpu0	Resets Cortex-A9 CPU0 in MPU. When software changes this field from 0 to 1, it triggers the following sequence: 1. CPU0 reset is asserted. cpu0 clkoff is de-asserted 2. after 32 osc1_clk cycles, cpu0 clkoff is asserted. When software changes this field from 1 to 0, it triggers the following sequence: 1. CPU0 reset is de-asserted. 2. after 32 cycles, cpu0 clkoff is de-asserted. Software needs to wait for at least 64 osc1_clk cycles between each change of this field to keep the proper reset/clkoff sequence.	RW	0x0

permodrst

The PERMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software. Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal. All fields are reset by a warm or cold reset. The reset value of all fields is 1. This holds the corresponding module in reset until software is ready to release the module from reset by writing 0 to its field.

The FPGA manager in the hard processor system (HPS) manages and monitors the FPGA portion of the system on a chip (SoC) device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

Features of the FPGA Manager

The FPGA manager provides the following functionality and features:

- Full configuration and partial reconfiguration of the FPGA portion of the SoC device
- Drives 32 general-purpose output signals to the FPGA fabric
- Receives 32 general-purpose input signals from the FPGA fabric
- Receives two boot handshaking input signals from the FPGA fabric (used when the HPS boots from the FPGA)
- Monitors the FPGA configuration and power status
- Generates interrupts based on the FPGA status changes
- Can reset the FPGA

FPGA Manager Block Diagram and System Integration

Figure 5-1: FPGA Manager Block Diagram

The register slave interface connects to the level 4 (L4) master peripheral bus for control and status register (CSR) access. The configuration slave interface connects to the level 3 (L3) interconnect for the microprocessor unit (MPU) subsystem or other masters to write the FPGA configuration image to the FPGA control block (CB) when configuring the FPGA portion of the SoC device.

The general-purpose I/O and boot handshake input interfaces connect to the FPGA fabric. The FPGA manager also connects to the FPGA CB signals to monitor and control the FPGA portion of the device.

The FPGA manager consists of the following blocks:

- Configuration slave interface—accepts and transfers the configuration image to the data interface.
- Register slave interface—accesses the CSRs in the FPGA manager.
- Data—accepts the FPGA configuration image from the configuration slave interface and sends it to the FPGA CB.
- Control—controls the FPGA CB.
- Monitor—monitors the configuration signals in the FPGA CB and sends interrupts to the MPU subsystem.
- Fabric I/O—reads and writes signals from or to the FPGA fabric.

Functional Description of the FPGA Manager

FPGA Manager Building Blocks

The FPGA manager has the two blocks - fabric I/O and monitor.

Related Information

[FPGA Manager Address Map and Register Definitions](#) on page 5-9

Fabric I/O

The fabric I/O block contains the following registers to allow simple low-latency communication between the HPS and the FPGA fabric:

- General-purpose input register (`gpi`)
- General-purpose output register (`gpo`)
- Boot handshaking input register (`misci`)

These registers are only valid when the FPGA is in user mode. Reading from these registers while the FPGA is not in user mode provides undefined data.

The 32 general-purpose input signals from the FPGA fabric are read by reading the `gpi` register using the register slave interface. The 32 general-purpose output signals to the FPGA fabric are generated from writes to the `gpo` register. For more information about FPGA manager registers, refer to [FPGA Manager Address Map and Register Definitions](#) on page 5-9.

The boot handshake input signals from the FPGA fabric are read by reading the `misci` register. The `f2h_boot_from_fpga_ready` signal indicates that the FPGA fabric is ready to send preloader information to the boot ROM. The `f2h_boot_from_fpga_on_failure` signal serves as a fallback in the event that the boot ROM code fails to boot from the primary boot flash device. In this case, the boot ROM code checks these two handshaking signals to determine if it should use the boot code hosted in the FPGA memory as the next stage in the boot process.

There is no interrupt support for this block.

Related Information

[FPGA Manager Address Map and Register Definitions](#) on page 5-9

Monitor

The monitor block is an instance of the SynopsysGPIO IP (DW_apb_gpio), which is a separate instance of the IP that comprises the three HPS GPIO interfaces. The monitor block connects to the configuration signals in the FPGA. This block monitors key signals related to FPGA configuration such as `INIT_DONE`, `CRC_ERROR`, and `PR_DONE`. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. The `mon` address map within the FPGA manager register address map contains the monitor registers. For more information about FPGA manager registers, refer to [FPGA Manager Address Map and Register Definitions](#) on page 5-9

You can program the FPGA manager to treat any of the monitor signals as interrupt sources. Independent of the interrupt source type, the monitor block always drives an active-high level interrupt to the MPU. Each interrupt source can be of the following types:

- Active-high level
- Active-low level
- Rising edge
- Falling edge

FPGA Configuration

You can configure the FPGA using an external device or through the HPS. This section highlights configuring the FPGA through the HPS.

The FPGA CB uses the FPGA mode select (`MSEL`) pins to determine which configuration scheme to use. The `MSEL` pins must be tied to the appropriate values for the configuration scheme. The table below lists supported `MSEL` values when the FPGA is configured by the HPS.

Table 5-1: Configuration Schemes for FPGA Configuration by the HPS

Configuration Scheme	Compression Feature	Design Security Feature	POR Delay ⁽¹⁰⁾	MSEL[4..0] ⁽¹¹⁾	cfgwidth	cdratio	Supports Partial Reconfiguration
FPP ×16	Disabled	AES Disabled	Fast	00000	0	1	Yes
			Standard	00100	0	1	Yes
	Disabled	AES Enabled	Fast	00001	0	2	Yes
			Standard	00101	0	2	Yes
	Enabled	Optional	Fast	00010	0	4	Yes
			Standard	00110	0	4	Yes
FPP ×32 ⁽¹³⁾	Disabled	AES Disabled	Fast	01000	1	1	No
			Standard	01100	1	1	No
	Disabled	AES Enabled	Fast	01001	1	4	No
			Standard	01101	1	4	No
	Enabled	Optional ⁽¹²⁾	Fast	01010	1	8	No
			Standard	01110	1	8	No

HPS software sets the clock-to-data ratio field (`cdratio`) and configuration data width bit (`cfgwidth`) in the control register (`ctrl`) to match the MSEL pins. The `cdratio` field and `cfgwidth` bit must be set before the start of configuration.

The FPGA manager connects to the configuration logic in the FPGA portion of the device using a mode similar to how external logic (for example, MAX II or an intelligent host) configures the FPGA in fast

⁽¹⁰⁾ For information about POR delay, refer to the Configuration, Design Security, and Remote System Upgrades in Cyclone V Devices.

⁽¹¹⁾ Other MSEL values are allowed when the FPGA is configured from a non-HPS source. For information, refer to the Configuration, Design Security, and Remote System Upgrades in Cyclone V Devices.

⁽¹²⁾ You can select to enable or disable this feature.

⁽¹³⁾ When the FPGA is configured through the HPS, then FPPx32 is supported. Otherwise, if the FPGA is configured from a non-HPS (external) source, then FPPx32 is not supported. For more information refer to the Configuration, Design Security, and Remote System Upgrades in Cyclone V Devices.

passive parallel (FPP) mode. FPGA configuration through the HPS supports all the capabilities of FPP mode, including the following items:

- FPGA configuration
- Partial FPGA reconfiguration
- FPGA I/O configuration, followed by PCI Express® (PCIe®) configuration of the remainder of FPGA
- External single event upset (SEU) scrubbing
- Decompression
- Advanced Encryption Standard (AES) encryption
- FPGA `DCLK` clock used for initialization phase clock

Configuring the FPGA portion of the SoC device comprises the following phases:

1. Power up phase
2. Reset phase
3. Configuration phase
4. Initialization phase
5. User mode

The FPGA Manager can be configured to accept configuration data directly from the MPU or the DMA engine. Either the processor or the DMA engine moves data from memory to the FPGA Manager data image register space `img_data_w`. The L4 interconnect allocates a 4 KB region for image data. It is not necessary to increment the address when writing the image data because all accesses within the 4 KB image data region will be transferred to the configuration logic.

- [Booting and Configuration](#) on page 31-1

Power Up Phase

In this phase, the VCC is ramping up and has yet to reach normal levels. This phase completes when the on-chip voltage detector determines that the VCC has reached normal levels.

Reset Phase

The FPGA manager resets the FPGA portion of the SoC device when the FPGA configuration signal (`nCONFIG`) is driven low. The HPS configures the FPGA by writing a 1 to the `nconfigpull` bit of the `ctrl` register. This action causes the FPGA portion of the device to reset and perform the following actions:

1. Clear the FPGA configuration RAM bits
2. Tri-state all FPGA user I/O pins
3. Pull the `nSTATUS` and `CONF_DONE` pins low
4. Use the FPGA CB to read the values of the `MSEL` pins to determine the configuration scheme

The `nconfigpull` bit of the `ctrl` register needs to be set to 0 when the FPGA has successfully entered the reset phase. Setting the bit releases the FPGA from the reset phase and transitions to the configuration phase.

Note: You must set the `cdratio` and `cfgwidth` bits of the `ctrl` register appropriately before the FPGA enters the reset phase.

Configuration Phase

To configure the FPGA using the HPS, software sets the `axicfggen` bit of the `ctrl` register to 1. Software then sends configuration data to the FPGA by writing data to the write data register (`data`) in the FPGA manager module configuration data address map. Software polls the `CONF_DONE` pin by reading the `gpio_instatus` register to determine if the FPGA configuration is successful. When configuration is successful, software sets the `axicfggen` bit of the `ctrl` register to 0. The FPGA user I/O pins are still tri-stated in this phase.

After successfully completing the configuration phase, the FPGA transitions to the initialization phase. To delay configuring the FPGA, set the `confdonepull` bit of the `ctrl` register to 1.

Related Information

[Booting and Configuration](#) on page 31-1

Initialization Phase

In this phase, the FPGA prepares to enter user mode. The internal oscillator in the FPGA portion of the device is the default clock source for the initialization phase. Alternatively, the configuration image can specify the `CLKUSR` or the `DCLK` pins as the clock source. The alternate clock source controls when the FPGA enters user mode.

If `DCLK` is selected as the clock source, software uses the `DCLK` count (`dclkcnt`) register to drive `DCLK` pulses to the FPGA. Writing to the `cnt` field of the `dclkcnt` register triggers the FPGA manager to generate the specified number of `DCLK` pulses. When all of the `DCLK` pulses have been sent, the `dcntdone` bit of the `DCLK` status (`dclkstat`) register is set to 1. Software polls the `dcntdone` bit to know when all of the `DCLK` pulses have been sent.

Note: Before another write to the `dclkcnt` register, software needs to write a value of 1 to the `dcntdone` bit to clear the done state.

The FPGA user I/O pins are still tri-stated in this phase. When the initialization phase completes, the FPGA releases the optional `INIT_DONE` pin and an external resistor pulls the pin high.

User Mode

The FPGA enters the user mode after exiting the initialization phase. The FPGA user I/O pins are no longer tri-stated in this phase and the configured soft logic in the FPGA becomes active.

The FPGA remains in user mode until the `nCONFIG` pin is driven low. If the `nCONFIG` pin is driven low, the FPGA reenters the reset phase. The internal oscillator is disabled in user mode, but is enabled as soon as the `nCONFIG` pin is driven low.

FPGA Status

Configuration signals from the FPGA CB such as `INIT_DONE`, `CRC_ERROR` and `PR_DONE` are monitored by the FPGA Manager. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. Monitored signals can be read through the `imgcfg_stat` register as well as the `intr_masked_status` register. Each of the monitored signals can generate an interrupt to the MPU global interrupt controller. Each interrupt source can be enabled and the polarity of the signals generating the interrupt can also be selected through the `intr_mask` and `intr_polarity` registers in the FPGA Manager.

Error Message Extraction

Cyclic redundancy check (CRC) errors from the FPGA fabric are monitored by the FPGA Manager. Upon assertion of a CRC error signal from the FPGA, the FPGA Manager extracts information about the error including:

- Error syndrome
- Error location
- Error type

A CRC error interrupt from the FPGA manager can be enabled through software. Software can then extract the CRC error information from the error message register (EMR) data interface. The number of valid error information bits in the EMR data registers depends on the specific FPGA device.

Boot Handshake

There are two input signals from the FPGA to control HPS boot from the FPGA. Both are synchronized within the FPGA Manager. Boot software reads these signals before accessing a boot image in the FPGA. The following table describes the functionality of these signals.

Signal	Description
<code>f2h_boot_from_fpga_on_failure</code>	Indicates whether a fallback preloader image is available in the FPGA on-chip RAM at memory location 0x0. The fallback preloader image is used only if the HPS boot ROM does not find a valid preloader image in the selected flash memory device. It is an active high signal which the bootrom polls when all the preloaders fail to load. This signal is driven low when the FPGA is not configured and it is up to you to drive it high in your user design.
<code>f2h_boot_from_fpga_ready</code>	Indicates a preloader image is available in an FPGA on-chip RAM at memory location 0x0 and it is ready to be accessed. It is an active high signal which the bootrom polls to determine when the FPGA is configured and the memory located at offset 0x0 from the F2H bridge is ready to be written to. When the FPGA is not configured the hardware will drive this signal low and it is up to you to drive it high when the memory in the FPGA is ready to accept memory mapped transactions.

General Purpose I/O

Thirty-two general purpose inputs and thirty-two general purpose outputs are provided to the FPGA and are controlled through registers in the FPGA Manager.

No interrupts are generated through the input pins. All inputs are synchronized within the FPGA Manager. Output signals should be synchronized in the FPGA.

Clock

The FPGA manager has two clock input signals which are asynchronous to each other. The clock manager generates these two clocks:

- `cfg_clk`—the configuration slave interface clock input and also the `DCLK` output reference for FPGA configuration. Enable this clock in the clock manager only when configuration is active or when the configuration slave interface needs to respond to master requests.
- `l4_mp_clk`—the register slave interface clock.

Related Information

[Clock Manager](#) on page 3-1

Reset

The FPGA manager has the `fpga_manager_rst_n` reset signal. The reset manager drives this signal to the FPGA manager on a cold or warm reset. All distributed reset signals in the FPGA manager are asserted asynchronously at the same time and deasserted synchronously to their associated clocks.

data

Used to send configuration image to FPGA. The DATA register accepts 4 bytes of the configuration image on each write. The configuration image byte-stream is converted into a 4-byte word with little-endian ordering. If the configuration image is not an integer multiple of 4 bytes, software should pad the configuration image with extra zero bytes to make it an integer multiple of 4 bytes. The FPGA Manager converts the DATA to 16 bits wide when writing CB.DATA for partial reconfiguration. The FPGA Manager waits to transmit the data to the CB until the FPGA is able to receive it. For a full configuration, the FPGA Manager waits until the FPGA exits the Reset Phase and enters the Configuration Phase. For a partial reconfiguration, the FPGA Manager waits until the CB.PR_READY signal indicates that the FPGA is ready.

stat

Provides status fields for software for the FPGA Manager. The Mode field tells software what configuration phase the FPGA currently is in. For regular configuration through the PINs or through the HPS, these states map directly to customer configuration documentation. For Configuration Via PCI Express (CVP), the IOCSR configuration is done through the PINS or through HPS. Then the complete configuration is done through the PCI Express Bus. When CVP is being done, InitPhase indicates only IOCSR configuration has completed. CVP_CONF_DONE is available in the CB Monitor for observation by software. The MSEL field provides a read only register for software to read the MSEL value driven from the external pins.

ctrl

Allows HPS to control FPGA configuration. The NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields drive signals to the FPGA Control Block that are logically ORed into their respective pins. These signals are always driven independent of the value of EN. The polarity of the NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields is inverted relative to their associated pins. The MSEL (external pins), CDRATIO and CFGWDTH signals determine the mode of operation for Normal Configuration. For Partial Reconfiguration, CDRATIO is used to set the appropriate clock to data ratio, and CFGWDTH should always be set to 16-bit Passive Parallel. AXICFGEN is used to enable transfer of configuration data by enabling or disabling DCLK during data transfers.

0x1	FPGA Manager drives configuration inputs to the CB. Used when HPS configures the FPGA.									

dclkcnt

Used to give software control in enabling DCLK at any time. SW will need control of the DCLK in specific configuration and partial reconfiguration initialization steps to send spurious DCLKs required by the CB. SW takes ownership for DCLK during normal configuration, partial reconfiguration, error scenerio handshakes including SEU CRC error during partial reconfiguration, SW early abort of partial reconfiguration, and initializatin phase DCLK driving. During initialization phase, a configuration image loaded into the FPGA can request that DCLK be used as the initialization phase clock instead of the default internal oscillator or optionally the CLKUSR pin. In the case that DCLK is requested, the DCLKCNT register is used by software to control DCLK during the initialization phase. Software should poll the DCLKSTAT.DCNTDONE write one to clear register to be set when the correct number of DCLKs

have completed. Software should clear DCLKSTAT.DCNTDONE before writing to the DCLKCNT register again. This field only affects the FPGA if CTRL.EN is 1.

Module Instance	Base Address	Register Address
fpgamgrregs	0xFF706000	0xFF706008

Offset: 0x8

dclkcnt Fields

Bit	Name	Description	Access	Reset
31:0	cnt	Controls DCLK counter. Software writes a non-zero value into CNT and the FPGA Manager generates the specified number of DCLK pulses and decrements COUNT. This register will read back the original value written by software. Software can write CNT at any time.	RW	0x0

dclkstat

This write one to clear register indicates that the DCLKCNT has counted down to zero. The DCLKCNT is used by software to drive spurious DCLKs to the FPGA. Software will poll this bit after writing DCLKCNT to know when all of the DCLKs have been sent.

Module Instance	Base Address	Register Address
fpgamgrregs	0xFF706000	0xFF70600C

Offset: 0xC

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Configuration Monitor (MON) Registers Register Descriptions

The Configuration Monitor allows software to poll or be interrupted by changes in the FPGA state. The Configuration Monitor is an instantiation of a Synopsys GPIO.

Only registers relevant to the MON operation are shown. The GPIO inputs are connected to the following signals:

- **nSTATUS** - Driven to 0 by the FPGA in this device if the FPGA is in Reset Phase or if the FPGA detected an error during the Configuration Phase.
- **CONF_DONE** - Driven to 0 by the FPGA in this device during the Reset Phase and driven to 1 when the FPGA Configuration Phase is done.
- **INIT_DONE** - Driven to 0 by the FPGA in this device during the Configuration Phase and driven to 1 when the FPGA Initialization Phase is done.
- **CRC_ERROR** - CRC error indicator. A **CRC_ERROR** value of 1 indicates that the FPGA detected a CRC error while in User Mode.
- **CVP_CONF_DONE** - Configuration via PCIe done indicator. A **CVP_CONF_DONE** value of 1 indicates that CVP is done.
- **PR_READY** - Partial reconfiguration ready indicator. A **PR_READY** value of 1 indicates that the FPGA is ready to receive partial reconfiguration or external scrubbing data.
- **PR_ERROR** - Partial reconfiguration error indicator. A **PR_ERROR** value of 1 indicates that the FPGA detected an error during partial reconfiguration or external scrubbing.
- **PR_DONE** - Partial reconfiguration done indicator. A **PR_DONE** value of 1 indicates partial reconfiguration or external scrubbing is done.
- **nCONFIG Pin** - Value of the **nCONFIG** pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the **nCONFIG** pin. See the description of the **nCONFIG** field in this register to understand when the FPGA in this device pulls-down the **nCONFIG** pin. Logic external to this device pulls-down the **nCONFIG** pin to put the FPGA into the Reset Phase.
- **nSTATUS Pin** - Value of the **nSTATUS** pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the **nSTATUS** pin. See the description of the **nSTATUS** field in this register to understand when the FPGA in this device pulls-down the **nSTATUS** pin. Logic external to this device pulls-down the **nSTATUS** pin during Configuration Phase or Initialization Phase if it detected an error.
- **CONF_DONE Pin** - Value of the **CONF_DONE** pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the **CONF_DONE** pin. See the description of the **CONF_DONE** field in this register to understand when the FPGA in this device pulls-down the **CONF_DONE** pin. See FPGA documentation to determine how logic external to this device drives **CONF_DONE**.
- **FPGA_POWER_ON** - FPGA powered on indicator
 - 0 = FPGA portion of device is powered off.
 - 1 = FPGA portion of device is powered on.

Offset: 0x800

[gpio_inten](#) on page 5-24

Allows each bit of Port A to be configured to generate an interrupt or not.

[gpio_intmask](#) on page 5-27

This register has 12 individual interrupt masks for the MON. Controls whether an interrupt on Port A can create an interrupt for the interrupt controller by not masking it. By default, all interrupts bits are unmasked. Whenever a 1 is written to a bit in this register, it masks the interrupt generation capability for this signal; otherwise interrupts are allowed through. The unmasked status can be read as well as the resultant status after masking.

[gpio_inttype_level](#) on page 5-30

The interrupt level register defines the type of interrupt (edge or level) for each GPIO input.

[gpio_int_polarity](#) on page 5-33

Controls the polarity of interrupts that can occur on each GPIO input.

[gpio_intstatus](#) on page 5-36

Reports on interrupt status for each GPIO input. The interrupt status includes the effects of masking.

[gpio_raw_intstatus](#) on page 5-39

Reports on raw interrupt status for each GPIO input. The raw interrupt status excludes the effects of masking.

[gpio_porta_eoi](#) on page 5-41

This register is written by software to clear edge interrupts generated by each individual GPIO input. This register always reads back as zero.

[gpio_ext_porta](#) on page 5-44

Reading this register reads the values of the GPIO inputs.

[gpio_ls_sync](#) on page 5-45

The Synchronization level register is used to synchronize inputs to the `l4_mp_clk`. All MON interrupts are already synchronized before the GPIO instance so it is not necessary to setup this register to enable synchronization.

[gpio_ver_id_code](#) on page 5-46

GPIO Component Version

[gpio_config_reg2](#) on page 5-47

Specifies the bit width of port A.

[gpio_config_reg1](#) on page 5-48

Reports settings of various GPIO configuration parameters

gpio_inten

Allows each bit of Port A to be configured to generate an interrupt or not.

gpio_inttype_level

The interrupt level register defines the type of interrupt (edge or level) for each GPIO input.

Module Instance	Base Address	Register Address
fpgamgrregs	0xFF706000	0xFF706838

Offset: 0x838

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Value	Description									
0x0	Inactive									
0x1	Active									

gpio_porta_eoi

This register is written by software to clear edge interrupts generated by each individual GPIO input. This register always reads back as zero.

Module Instance	Base Address	Register Address
fpgamgrregs	0xFF706000	0xFF70684C

Offset: 0x84C

Access: WO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

The system manager in the hard processor system (HPS) contains memory-mapped control and status registers (CSRs) and logic to control system level functions as well as other modules in the HPS.

The system manager connects to the following modules in the HPS:

- Direct memory access (DMA) controller
- Ethernet media access controllers (EMAC0 and EMAC1)
- Microprocessor unit (MPU) subsystem
- NAND flash controller
- Secure Digital/MultiMediaCard (SD/MMC) controller
- Quad serial peripheral interface (SPI) flash controller
- USB 2.0 On-The-Go (OTG) controllers (USB0 and USB1)
- Watchdog timers

Features of the System Manager

Software accesses the CSRs in the system manager to control and monitor various functions in other HPS modules that require external control signals. The system manager connects to these modules to perform the following functions:

- Sends pause signals to pause the watchdog timers when the processors in the MPU subsystem are in debug mode
- Selects the EMAC level 3 (L3) master signal options.
- Freezes the I/O pins after the HPS comes out of cold reset and during serial configuration.
- Selects the SD/MMC controller clock options and L3 master signal options.
- Selects the NAND flash controller bootstrap options and L3 master signal options.
- Selects USB controller L3 master signal options.
- Provides control over the DMA security settings when the HPS exits from reset.
- Provides boot source and clock source information that can be read during the boot process.
- Provides the capability to enable or disable an interface to the FPGA.
- Routes parity failure interrupts from the L1 caches to the Global Interrupt Controller.
- Sends error correction code (ECC) enable signals to all HPS modules with ECC-protected RAM.
- Provides the capability to inject errors during testing in the MPU L2 ECC-protected RAM.

System Manager Block Diagram and System Integration

The system manager connects to the level 4 (L4) bus through a slave interface. The CSRs connect to signals in the FPGA and other HPS modules.

Figure 6-1: System Manager Block Diagram

The system manager consists of the following:

- CSRs—Provide memory-mapped access to control signals and status for the following HPS modules:
 - EMACs
 - Debug core
 - SD/MMC controller
 - NAND controller
 - USB controllers
 - DMA controller
 - System interconnect
 - ECC memory interfaces for the following peripherals:
 - USB controllers
 - SD/MMC controller
 - Ethernet MACs
 - DMA controller
 - NAND flash controller
 - On-chip RAM
- Slave port interface—provides access to system manager CSRs for connected masters.
- Watchdog debug pause—accepts the debug mode status from the MPU subsystem and pauses the L4 watchdog timers.
- Reset Manager— system manager receives the reset signals from reset manager.

Functional Description of the System Manager

The system manager serves the following purposes:

- Provides software access to boot configuration and system information
- Provides software access to control and status signals in other HPS modules
- Provides combined ECC status and interrupt from other HPS modules with ECC-protected RAM
- Enables and disables HPS peripheral interfaces to the FPGA
- Provides eight registers that software can use to pass information between boot stages

Boot Configuration and System Information

The system manager provides boot configuration information through the `bootinfo` register. Sampled value of the HPS boot select (`BSEL`) pins are available to the Boot ROM software.

The boot source is determined by the `BSEL` pins.

Related Information

[Booting and Configuration](#) on page 31-1

Additional Module Control

Each module in the HPS has its own CSRs, providing access to the internal state of the module. The system manager provides registers for additional module control and monitoring. To fully control each module,

you must program both the peripheral's CSR and its corresponding CSR in the System Manager. This section describes how to configure the system manager CS for each module.

DMA Controller

The security state of the DMA controller is controlled by the manager thread security (`mgr_ns`) and interrupt security (`irq_ns`) bits of the DMA register.

The `periph_ns` register bits determine if a peripheral request interface is secure or non-secure.

Note: The `periph_ns` register bits must be configured before the DMA is released from global reset.

Related Information

- [DMA Controller](#) on page 17-1
- [System Manager Address Map and Register Definitions](#) on page 6-9

NAND Flash Controller

The bootstrap control register (`nand_bootstrap`) modifies the default behavior of the NAND flash controller after reset. The NAND flash controller samples the bootstrap control register bits when it comes out of reset.

The following `nand_bootstrap` register bits control configuration of the NAND flash controller:

- Bootstrap inhibit initialization bit (`noinit`)—inhibits the NAND flash controller from initializing when coming out of reset, and allows software to program all registers pertaining to device parameters such as page size and width.
- Bootstrap 512-byte device bit (`page512`)—informs the NAND flash controller that a NAND flash device with a 512-byte page size is connected to the system.
- Bootstrap inhibit load block 0 page 0 bit (`noloadb0p0`)—inhibits the NAND flash controller from loading page 0 of block 0 of the NAND flash device during the initialization procedure.
- Bootstrap two row address cycles bit (`tworowaddr`)—informs the NAND flash controller that only two row address cycles are required instead of the default three row address cycles.

You can use the system manager's `nanad_l3master` register to control the following signals:

- ARPROT
- AWPROT
- ARDOMAIN
- AWDOMAIN
- ARCACHE
- AWCACHE

These bits define the cache attributes for the master transactions of the DMA engine in the NAND controller.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

- [NAND Flash Controller](#) on page 14-1
- [System Manager Address Map and Register Definitions](#) on page 6-9

CAN Controller

The switching between the CAN controller and FPGA interfaces is controlled by the system manager. The DMA channels can be dedicated to the FPGA or to one of the four CAN interfaces.

Table 6-1: Peripheral Request Interface Mapping

DMA Channel	Peripheral	CAN Controller
Channel 0	FPGA 4	CAN0 interface 1
Channel 1	FPGA 5	CAN0 interface 2
Channel 2	FPGA 6	CAN1 interface 1
Channel 3	FPGA 7	CAN1 interface 2

The `ctrl` register controls the MUX that selects whether FPGA or CAN connects to each of the DMA peripheral request interfaces.

Table 6-2: Control Register (ctrl)

Interface	Value
FPGA	0x0
CAN	0x1

For more information on the System Manger's registers, refer to the *Cyclone V SoC HPS Address Map and Register Definitions* page.

EMAC

You can program the `emac_global` register to select either `emac_ptp_clk` from the Clock Manager or `f2s_ptp_ref_clk` from the FPGA fabric as the source of the IEEE 1588 reference clock for each EMAC.

You can use the system manager's `l3master` register to control the EMAC's `ARCACHE` and `AWCACHE` signals, by setting or clearing the (`arcache`, `awcache`) bits. These bits define the cache attributes for the master transactions of the DMA engine in the EMAC controllers.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

The `phy_intf_sel` bit is programmed to select between a GMII (MII), RGMII or RMII PHY interface when the peripheral is released from reset. The `ptp_ref_sel` bit selects if the timestamp reference is internally or externally generated. The `ptp_ref_sel` bit must be set to the correct value before the EMAC core is pulled out of reset.

Related Information

USB 2.0 OTG Controller

The `usb*_l3master` registers in the system manager control the `HPROT` and `HAUSER` fields of the USB master port of the USB 2.0 OTG Controller.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

[USB 2.0 OTG Controller](#) on page 19-1

SD/MMC Controller

The `sdmmc_l3master` register in the system manager controls the `HPROT` and `HAUSER` fields of the SD/MMC master port.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

You can program software to select the clock's phase shift for `cclk_in_drv` and `cclk_in_sample` by setting the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smpsel`) bits of the `sdmmc` register in the system manager.

Related Information

[SD/MMC Controller](#) on page 15-1

Watchdog Timer

The system manager controls the watchdog timer behavior when the CPUs are in debug mode. The system manager sends a pause signal to the watchdog timers depending on the setting of the debug mode bits of the L4 watchdog debug register (`wddbfg`). Each watchdog timer built into the MPU subsystem is paused when its associated CPU enters debug mode.

Related Information

[Watchdog Timer](#) on page 25-1

Boot ROM Code

Registers in the system manager control whether the boot ROM code configures the pin multiplexing for boot pins after a warm reset. Set the warm-reset-configure-pin-multiplex for boot pins bit (`warmrstcfg-pinmux`) of the boot ROM code register to enable or disable this control.

Note: The boot ROM code always configures the pin multiplexing for boot pins after a cold reset.

Registers in the system manager also control whether the boot ROM code configures the I/O pins used during the boot process after a warm reset. Set the warm reset configure I/Os for boot pins bit (`warmrstcfggio`) of the `ctrl` register to enable or disable this control.

Note: By default, the boot ROM code always configures the I/O pins used by boot after a cold reset.

When CPU1 is released from reset and the boot ROM code is located at the CPU1 reset exception address (for a typical case), the boot ROM reset handler code reads the address stored in the CPU1 start address register (`cpu1startaddr`) and passes control to software at that address.

There can be up to four preloader images stored in flash memory. The (`initswlastld`) register contains the index of the preloader's last image that is loaded in the on-chip RAM.

The boot ROM software state register (`bootromswstate`) is a 32-bit general-purpose register reserved for the boot ROM.

The following warmram related registers are used to configure the warm reset from on-chip RAM feature and must be written by software prior to the warm reset occurring.

Table 6-3: The warmram Registers

Register	Name	Purpose
<code>enable</code>	Enable	Controls whether the boot ROM attempts to boot from the contents of the on-chip RAM on a warm reset.
<code>datastart</code>	Data start	Contains the byte offset of the warm boot CRC validation region in the on-chip RAM. The offset must be word-aligned to an integer multiple of four.
<code>length</code>	Length	Contains the length in bytes of the region in the on-chip RAM available for warm boot CRC validation.
<code>execution</code>	Execution offset	Contains a 16-bit offset into the on-chip RAM that the boot code jumps to if the CRC validation succeeds. The boot ROM appends 0xFFFF to the upper 16-bits of this 32-bit register value when it is read.
<code>crc</code>	Expected CRC	Contains the expected CRC of the region in the on-chip RAM.

The number of wait states applied to the boot ROM's read operation is determined by the wait state bit (`waitstate`) of the `ctrl` register. After the boot process, software might require reading the code in the boot ROM. If software has changed the clock frequency of the `l3_main_clk` after reset, an additional wait state is necessary to access the boot ROM. Set the `waitstate` bit to add an additional wait state to the read access of the boot ROM. The enable safe mode warm reset update bit controls whether the wait state bit is updated during a warm reset.

L3 Interconnect

The System Manager provides remap bits to the L3 interconnect. These bits can remap the Boot ROM and the On-chip RAM.

FPGA Interface Enables

The system manager can enable or disable interfaces between the FPGA and HPS.

The global interface bit (`intf`) of the global disable register (`gbl`) disables all interfaces between the FPGA and HPS.

Note: Ensure that the FPGA is configured before enabling the interfaces and that all interfaces between the FPGA and HPS are inactive before disabling them.

You can program the individual disable register (`indiv`) to disable the following interfaces between the FPGA and HPS:

You can program the FPGA interface enable registers (`fpga_intf_en_*`) to disable the following interfaces between the FPGA and HPS:

- Reset request interface
- JTAG enable interface
- I/O configuration interface
- Boundary scan interface
- Debug interface
- Trace interface
- System Trace Macrocell (STM) interface
- Cross-trigger interface (CTI)
- QSPI interface
- SD/MMC interface
- SPI Master interface
- SPI Slave interface
- EMAC interface
- UART interface
- CAN interface

ECC and Parity Control

The system manager can enable or disable ECC for each of the following HPS modules with ECC-protected RAM:

- MPU L2 cache data RAM
- On-chip RAM
- USB 2.0 OTG controller (USB0 and USB1) RAM
- EMAC (EMAC0 and EMAC1) RAM
- DMA controller RAM
- CAN controller RAM
- NAND flash controller RAM
- Quad SPI flash controller RAM
- SD/MMC controller RAM
- DDR interfaces

The system manager can inject single-bit or double-bit errors into the MPU L2 ECC memories for testing purposes. Set the bits in the appropriate memory enable register to inject errors. For example, to inject a single bit ECC error, set the `injs` bit of the `mpu_ctrl_l2_eccregister`.

Note: The injection request is edge-sensitive, meaning that the request is latched on 0 to 1 transitions on the injection bit. The next time a write operation occurs, the data will be corrupted, containing

either a single or double bit error as selected. When the data is read back, the ECC logic detects the single or double bit error appropriately. The injection request cannot be cancelled, and the number of injections is limited to once every five MPU cycles.

The system manager can also inject parity failures into the parity-protected RAM in the MPU L1 to test the parity failure interrupt handler. Set the bits of the parity fail injection register (`parityinj`) to inject parity failures.

Note: Injecting parity failures into the parity-protected RAM in the MPU L1 causes the interrupt to be raised immediately. There is no actual error injected and the data is not corrupted. Furthermore, there is no need for a memory operation to actually be performed for the interrupt to be raised.

Preloader Handoff Information

The system manager provides eight 32-bit registers to store handoff information between the preloader and the operating system. The preloader can store any information in these registers. These register contents have no impact on the state of the HPS hardware. When the operating system kernel boots, it retrieves the information by reading the preloader to OS handoff information register array. These registers are reset only by a cold reset.

Clocks

The system manager is driven by a clock generated by the clock manager.

Related Information

[Clock Manager](#) on page 3-1

Resets

The system manager receives two reset signals from the reset manager. The `sys_manager_rst_n` signal is driven on a cold or warm reset and the `sys_manager_cold_rst_n` signal is driven only on a cold reset. This function allows the system manager to reset some CSR fields on either a cold or warm reset and others only on a cold reset.

wddbq

Controls the behavior of the L4 watchdogs when the CPUs are in debug mode. These control registers are used to drive the pause input signal of the L4 watchdogs. Note that the watchdogs built into the MPU automatically are paused when their associated CPU enters debug mode. Only reset by a cold reset.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08010

Offset: 0x10

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset
15	btac_1	If 1, injecting parity error to BTAC RAM. The field array index corresponds to the CPU index.	RW	0x0
14	btac_0	If 1, injecting parity error to BTAC RAM. The field array index corresponds to the CPU index.	RW	0x0
13	ghb_1	If 1, injecting parity error to GHB RAM. The field array index corresponds to the CPU index.	RW	0x0
12	ghb_0	If 1, injecting parity error to GHB RAM. The field array index corresponds to the CPU index.	RW	0x0
11	ictag_1	If 1, injecting parity error to Instruction Cache Tag RAM. The field array index corresponds to the CPU index.	RW	0x0
10	ictag_0	If 1, injecting parity error to Instruction Cache Tag RAM. The field array index corresponds to the CPU index.	RW	0x0
9	icdata_1	If 1, injecting parity error to Instruction Cache Data RAM. The field array index corresponds to the CPU index.	RW	0x0
8	icdata_0	If 1, injecting parity error to Instruction Cache Data RAM. The field array index corresponds to the CPU index.	RW	0x0
7	maintlb_1	If 1, injecting parity error to Main TLB RAM. The field array index corresponds to the CPU index.	RW	0x0
6	maintlb_0	If 1, injecting parity error to Main TLB RAM. The field array index corresponds to the CPU index.	RW	0x0
5	dcouter_1	If 1, injecting parity error to Data Cache Outer RAM. The field array index corresponds to the CPU index.	RW	0x0
4	dcouter_0	If 1, injecting parity error to Data Cache Outer RAM. The field array index corresponds to the CPU index.	RW	0x0
3	dctag_1	If 1, injecting parity error to Data Cache Tag RAM. The field array index corresponds to the CPU index.	RW	0x0

Bit	Name	Description	Access	Reset
2	dctag_0	If 1, injecting parity error to Data Cache Tag RAM. The field array index corresponds to the CPU index.	RW	0x0
1	dcdata_1	If 1, injecting parity error to Data Cache Data RAM. The field array index corresponds to the CPU index.	RW	0x0
0	dcdata_0	If 1, injecting parity error to Data Cache Data RAM. The field array index corresponds to the CPU index.	RW	0x0

FPGA Interface Group Register Descriptions

Registers used to enable/disable interfaces between the FPGA and HPS. Required for either of the following situations: (1) Interfaces that cannot be disabled by putting an HPS module associated with the interface into reset; or (2) HPS modules that accept signals from the FPGA fabric and those signals might interfere with the normal operation of the module. All registers are only reset by a cold reset (ignore warm reset).

Offset: 0x20

gbl on page 6-30

Used to disable all interfaces between the FPGA and HPS.

indiv on page 6-31

Used to disable individual interfaces between the FPGA and HPS.

module on page 6-34

Used to disable signals from the FPGA fabric to individual HPS modules.

gbl

Used to disable all interfaces between the FPGA and HPS.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08020

Offset: 0x20

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

indiv Fields

Bit	Name	Description	Access	Reset
7	crosstrigintf	Used to disable the FPGA Fabric from sending triggers to HPS debug logic. Note that this doesn't prevent the HPS debug logic from sending triggers to the FPGA Fabric. Value Description 0x0 FPGA Fabric cannot send triggers. 0x1 FPGA Fabric can send triggers.	RW	0x1
6	stmeventintf	Used to disable the STM event interface. This interface allows logic in the FPGA fabric to trigger events to the STM debug module in the HPS. Value Description 0x0 STM event interface is disabled. Logic in the FPGA fabric cannot trigger STM events. 0x1 STM event interface is enabled. Logic in the FPGA fabric can trigger STM events.	RW	0x1
4	traceintf	Used to disable the trace interface. This interface allows the HPS debug logic to send trace data to logic in the FPGA fabric. Value Description 0x0 Trace interface is disabled. HPS debug logic cannot send trace data to the FPGA fabric. 0x1 Trace interface is enabled. Other registers in the HPS debug logic must be programmed to actually send trace data to the FPGA fabric.	RW	0x1

Bit	Name	Description	Access	Reset						
3	bscanintf	<p>Used to disable the boundary-scan interface. This interface allows the FPGA JTAG TAP controller to execute boundary-scan instructions such as SAMPLE/PRELOAD, EXTEST, and HIGHZ. The boundary-scan interface must be enabled before attempting to send the boundary-scan instructions to the FPGA JTAG TAP controller.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Boundary-scan interface is disabled. Execution of boundary-scan instructions in the FPGA JTAG TAP controller is unsupported and produces undefined results.</td> </tr> <tr> <td>0x1</td> <td>Boundary-scan interface is enabled. Execution of the boundary-scan instructions in the FPGA JTAG TAP controller is supported.</td> </tr> </tbody> </table>	Value	Description	0x0	Boundary-scan interface is disabled. Execution of boundary-scan instructions in the FPGA JTAG TAP controller is unsupported and produces undefined results.	0x1	Boundary-scan interface is enabled. Execution of the boundary-scan instructions in the FPGA JTAG TAP controller is supported.	RW	0x1
Value	Description									
0x0	Boundary-scan interface is disabled. Execution of boundary-scan instructions in the FPGA JTAG TAP controller is unsupported and produces undefined results.									
0x1	Boundary-scan interface is enabled. Execution of the boundary-scan instructions in the FPGA JTAG TAP controller is supported.									
2	configiointf	<p>Used to disable the CONFIG_IO interface. This interface allows the FPGA JTAG TAP controller to execute the CONFIG_IO instruction and configure all device I/Os (FPGA and HPS). This is typically done before executing boundary-scan instructions. The CONFIG_IO interface must be enabled before attempting to send the CONFIG_IO instruction to the FPGA JTAG TAP controller.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>CONFIG_IO interface is disabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is unsupported and produces undefined results.</td> </tr> <tr> <td>0x1</td> <td>CONFIG_IO interface is enabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is supported.</td> </tr> </tbody> </table>	Value	Description	0x0	CONFIG_IO interface is disabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is unsupported and produces undefined results.	0x1	CONFIG_IO interface is enabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is supported.	RW	0x1
Value	Description									
0x0	CONFIG_IO interface is disabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is unsupported and produces undefined results.									
0x1	CONFIG_IO interface is enabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is supported.									
1	jtagenintf	<p>Used to disable the JTAG enable interface (the fpgajtagen bit in the ctrl register). This interface allows logic in the FPGA fabric to disable the HPS JTAG operation.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disables the fpgajtagen bit found in the ctrl register.</td> </tr> <tr> <td>0x1</td> <td>Enables the fpgajtagen bit found in the ctrl register.</td> </tr> </tbody> </table>	Value	Description	0x0	Disables the fpgajtagen bit found in the ctrl register.	0x1	Enables the fpgajtagen bit found in the ctrl register.	RW	0x1
Value	Description									
0x0	Disables the fpgajtagen bit found in the ctrl register.									
0x1	Enables the fpgajtagen bit found in the ctrl register.									

Bit	Name	Description	Access	Reset						
0	rstreqintf	<p>Used to disable the reset request interface. This interface allows logic in the FPGA fabric to request HPS resets. This field disables the following reset request signals from the FPGA fabric to HPS:[list] [*]f2h_cold_rst_req_n - Triggers a cold reset of the HPS[*]f2h_warm_rst_req_n - Triggers a warm reset of the HPS[*]f2h_dbg_rst_req_n - Triggers a debug reset of the HPS[/list]</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Reset request interface is disabled. Logic in the FPGA fabric cannot reset the HPS.</td> </tr> <tr> <td>0x1</td> <td>Reset request interface is enabled. Logic in the FPGA fabric can reset the HPS.</td> </tr> </tbody> </table>	Value	Description	0x0	Reset request interface is disabled. Logic in the FPGA fabric cannot reset the HPS.	0x1	Reset request interface is enabled. Logic in the FPGA fabric can reset the HPS.	RW	0x1
Value	Description									
0x0	Reset request interface is disabled. Logic in the FPGA fabric cannot reset the HPS.									
0x1	Reset request interface is enabled. Logic in the FPGA fabric can reset the HPS.									

module

Used to disable signals from the FPGA fabric to individual HPS modules.

Freeze Control Group Register Descriptions

Registers used to generate HPS IO freeze signals. All registers are only reset by a cold reset (ignore warm reset).

Offset: 0x40

vioctrl on page 6-37

Used to drive freeze signals to HPS VIO banks. The register array index corresponds to the freeze channel. Freeze channel 0 provides freeze signals to VIO bank 0 and 1. Freeze channel 1 provides freeze signals to VIO bank 2 and 3. Only drives freeze signals when SRC.VIO1 is set to SW. Freeze channel 2 provides freeze signals to VIO bank 4. All fields are only reset by a cold reset (ignore warm reset). The following equation determines when the weak pullup resistor is enabled: $enabled = \sim wkpullup \mid (CFF \& cfg \& tristate)$ where CFF is the value of weak pullup as set by IO configuration

hioctrl on page 6-39

Used to drive freeze signals to HPS HIO bank (DDR SDRAM). All fields are only reset by a cold reset (ignore warm reset). The following equation determines when the weak pullup resistor is enabled: $enabled = \sim wkpullup \mid (CFF \& cfg \& tristate)$ where CFF is the value of weak pullup as set by IO configuration

src on page 6-41

Contains register field to choose between software state machine (vioctrl array index [1] register) or hardware state machine in the Freeze Controller as the freeze signal source for VIO channel 1. All fields are only reset by a cold reset (ignore warm reset).

hwctrl on page 6-42

Activate freeze or thaw operations on VIO channel 1 (HPS IO bank 2 and bank 3) and monitor for completeness and the current state. These fields interact with the hardware state machine in the Freeze Controller. These fields can be accessed independent of the value of SRC1.VIO1 although they only have an effect on the VIO channel 1 freeze signals when SRC1.VIO1 is setup to have the hardware state machine be the freeze signal source. All fields are only reset by a cold reset (ignore warm reset).

vioctrl

Used to drive freeze signals to HPS VIO banks. The register array index corresponds to the freeze channel. Freeze channel 0 provides freeze signals to VIO bank 0 and 1. Freeze channel 1 provides freeze signals to VIO bank 2 and 3. Only drives freeze signals when SRC.VIO1 is set to SW. Freeze channel 2 provides freeze signals to VIO bank 4. All fields are only reset by a cold reset (ignore warm reset). The following

equation determines when the weak pullup resistor is enabled: $\text{enabled} = \sim\text{wkpullup} \mid (\text{CFF} \ \& \ \text{cfg} \ \& \ \text{tristate})$ where CFF is the value of weak pullup as set by IO configuration

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08040

Offset: 0x40

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

0x1	Enables IO configuration as previously configured by software using the Scan Manager.									

src

Contains register field to choose between software state machine (vioctrl array index [1] register) or hardware state machine in the Freeze Controller as the freeze signal source for VIO channel 1. All fields are only reset by a cold reset (ignore warm reset).

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08054

Offset: 0x54

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

0	viol	<p>The freeze signal source for VIO channel 1 (VIO bank 2 and bank 3).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>VIO1 freeze signals are driven by software writing to the VIOCTRL[1] register. The VIO1-related fields in the hwctrl register are active but don't effect the VIO1 freeze signals.</td> </tr> <tr> <td>0x1</td> <td>VIO1 freeze signals are driven by the hardware state machine in the Freeze Controller. The VIO1-related fields in the hwctrl register are active and effect the VIO1 freeze signals.</td> </tr> </tbody> </table>	Value	Description	0x0	VIO1 freeze signals are driven by software writing to the VIOCTRL[1] register. The VIO1-related fields in the hwctrl register are active but don't effect the VIO1 freeze signals.	0x1	VIO1 freeze signals are driven by the hardware state machine in the Freeze Controller. The VIO1-related fields in the hwctrl register are active and effect the VIO1 freeze signals.	RW	0x0
Value	Description									
0x0	VIO1 freeze signals are driven by software writing to the VIOCTRL[1] register. The VIO1-related fields in the hwctrl register are active but don't effect the VIO1 freeze signals.									
0x1	VIO1 freeze signals are driven by the hardware state machine in the Freeze Controller. The VIO1-related fields in the hwctrl register are active and effect the VIO1 freeze signals.									

hwctrl

Activate freeze or thaw operations on VIO channel 1 (HPS IO bank 2 and bank 3) and monitor for completeness and the current state. These fields interact with the hardware state machine in the Freeze Controller. These fields can be accessed independent of the value of SRC1.VIO1 although they only have an effect on the VIO channel 1 freeze signals when SRC1.VIO1 is setup to have the hardware state machine be the freeze signal source. All fields are only reset by a cold reset (ignore warm reset).

DMA Controller Group Register Descriptions

Registers used by the DMA Controller to enable secured system support and select DMA channels.

Offset: 0x70

[ctrl](#) on page 6-51

Registers used by the DMA Controller. All fields are reset by a cold or warm reset. These register bits should be updated during system initialization prior to removing the DMA controller from reset. They may not be changed dynamically during DMA operation.

[persecurity](#) on page 6-52

Controls the security state of a peripheral request interface. Sampled by the DMA controller when it exits from reset. These register bits should be updated during system initialization prior to removing the DMA controller from reset. They may not be changed dynamically during DMA operation.

ctrl

Registers used by the DMA Controller. All fields are reset by a cold or warm reset. These register bits should be updated during system initialization prior to removing the DMA controller from reset. They may not be changed dynamically during DMA operation.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08070

Offset: 0x70

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Boot ROM Code Register Group Register Descriptions

Registers used by the Boot ROM code. All fields are only reset by a cold reset (ignore warm reset).

Offset: 0xc0

ctrl on page 6-54

Contains information used to control Boot ROM code.

cpu1startaddr on page 6-56

When CPU1 is released from reset and the Boot ROM is located at the CPU1 reset exception address (the typical case), the Boot ROM reset handler code reads the address stored in this register and jumps it to hand off execution to user software.

initswstate on page 6-57

The preloader software (loaded by the Boot ROM) writes the magic value 0x49535756 (ISWV in ASCII) to this register when it has reached a valid state.

initswlastld on page 6-57

Contains the index of the last preloader software image loaded by the Boot ROM from the boot device.

bootromswstate on page 6-58

32-bits general purpose register used by the Boot ROM code. Actual usage is defined in the Boot ROM source code.

Warm Boot from On-Chip RAM Group Register Descriptions on page 6-58

Registers used by the Boot ROM code to support booting from the On-chip RAM on a warm reset. All these registers must be written by user software before a warm reset occurs to make use of this feature.

ctrl

Contains information used to control Boot ROM code.

enable Fields

Bit	Name	Description	Access	Reset						
31:0	magic	Controls whether Boot ROM will attempt to boot from the contents of the On-chip RAM on a warm reset. When this feature is enabled, the Boot ROM code will not configure boot IOs, the pin mux, or clocks. Note that the enable value is a 32-bit magic value (provided by the enum). <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Boot ROM code will not attempt to boot from On-chip RAM on a warm reset</td> </tr> <tr> <td>0xae9efebc</td> <td>Boot ROM code will attempt to boot from On-chip RAM on a warm reset</td> </tr> </tbody> </table>	Value	Description	0x0	Boot ROM code will not attempt to boot from On-chip RAM on a warm reset	0xae9efebc	Boot ROM code will attempt to boot from On-chip RAM on a warm reset	RW	0x0
Value	Description									
0x0	Boot ROM code will not attempt to boot from On-chip RAM on a warm reset									
0xae9efebc	Boot ROM code will attempt to boot from On-chip RAM on a warm reset									

datastart

Offset into On-chip RAM of the start of the region for CRC validation

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080E4

Offset: 0xE4

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset															
RW 0x0															

datastart Fields

Bit	Name	Description	Access	Reset
15:0	offset	Contains the byte offset into the On-chip RAM of the start of the On-chip RAM region for the warm boot CRC validation. The offset must be an integer multiple of 4 (i.e. aligned to a word). The Boot ROM code will set the top 16 bits to 0xFFFF and clear the bottom 2 bits.	RW	0x0

length

Length of region in On-chip RAM for CRC validation.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080E8

Offset: 0xE8

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
size															
RW 0x0															

length Fields

Bit	Name	Description	Access	Reset
15:0	size	Contains the length (in bytes) of the region in the On-chip RAM for the warm boot CRC validation. If the length is 0, the Boot ROM won't perform CRC calculation and CRC check to avoid overhead caused by CRC validation. If the START + LENGTH exceeds the maximum offset into the On-chip RAM, the Boot ROM won't boot from the On-chip RAM. The length must be an integer multiple of 4. The Boot ROM code will clear the top 16 bits and the bottom 2 bits.	RW	0x0

execution

Offset into On-chip RAM to enter to on a warm boot.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080EC

Offset: 0xEC

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

offset															
RW 0x0															

execution Fields

Bit	Name	Description	Access	Reset
15:0	offset	Contains the byte offset into the On-chip RAM that the Boot ROM jumps to if the CRC validation succeeds. The Boot ROM code sets the top 16 bits to 0xFFFF when it reads this register, but does not change the contents of this register.	RW	0x0

crc

Length of region in On-chip RAM for CRC validation.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080F0

Offset: 0xF0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
expected RW 0xE763552A															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
expected RW 0xE763552A															

crc Fields

Bit	Name	Description	Access	Reset
31:0	expected	Contains the expected CRC of the region in the On-chip RAM. The Boot ROM code calculates the actual CRC for all bytes in the region specified by the DATA START an LENGTH registers. The contents of the EXECUTION register (after it has been read and modified by the Boot ROM code) is also included in the CRC calculation. The contents of the EXECUTION register is added to the CRC accumulator a byte at a time starting with the least significant byte. If the actual CRC doesn't match the expected CRC value in this register, the Boot ROM won't boot from the On-chip RAM. The CRC is a standard CRC32 with the polynomial: $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ There is no reflection of the bits and the initial value of the remainder is 0xFFFFFFFF and the final value is exclusive ORed with 0xFFFFFFFF.	RW	0xE763552A

Boot ROM Hardware Register Group Register Descriptions

Registers used by the Boot ROM hardware, not the code within it.

Offset: 0x100

ctrl on page 6-63

Controls behavior of Boot ROM hardware. All fields are only reset by a cold reset (ignore warm reset).

NAND Flash Controller Register Group Register Descriptions

Registers related to NAND Flash Controller which aren't located in the NAND Flash Controller itself.

Offset: 0x110

bootstrap on page 6-68

Bootstrap fields sampled by NAND Flash Controller when released from reset. All fields are reset by a cold or warm reset.

l3master on page 6-69

Controls the L3 master ARCACHE and AWCACHE AXI signals. These register bits should be updated only during system initialization prior to removing the peripheral from reset. They may not be changed dynamically during peripheral operation. All fields are reset by a cold or warm reset.

bootstrap

Bootstrap fields sampled by NAND Flash Controller when released from reset. All fields are reset by a cold or warm reset.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08110

Offset: 0x110

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

												RW 0x0	RW 0x0	RW 0x0	RW 0x0

bootstrap Fields

Bit	Name	Description	Access	Reset
3	tworowaddr	If 1, NAND device requires only 2 row address cycles instead of the normal 3 row address cycles.	RW	0x0
2	noloadb0p0	If 1, inhibits NAND Flash Controller from loading page 0 of block 0 of the NAND device as part of the initialization procedure.	RW	0x0
1	page512	If 1, NAND device has a 512 byte page size.	RW	0x0
0	noinit	If 1, inhibits NAND Flash Controller from performing initialization when coming out of reset. Instead, software must program all registers pertaining to device parameters like page size, width, etc.	RW	0x0

I3master

Controls the L3 master ARCACHE and AWCACHE AXI signals. These register bits should be updated only during system initialization prior to removing the peripheral from reset. They may not be changed dynamically during peripheral operation. All fields are reset by a cold or warm reset.

Module Instance	Base Address	Register Address

ECC Management Register Group Register Descriptions

ECC error status and control for all ECC-protected HPS RAM blocks.

Offset: 0x140

[l2](#) on page 6-74

This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register is reset by a cold reset (ignores warm reset). The interrupt status of the L2 ECC single/double bit error is handled in the General Interrupt Controller (GIC).

[ocram](#) on page 6-75

This register is used to enable ECC on the On-chip RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

[usb0](#) on page 6-76

This register is used to enable ECC on the USB0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

[usb1](#) on page 6-77

This register is used to enable ECC on the USB1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

[emac0](#) on page 6-78

This register is used to enable ECC on the EMAC0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

emac1 on page 6-80

This register is used to enable ECC on the EMAC1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

dma on page 6-82

This register is used to enable ECC on the DMA RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

can0 on page 6-83

This register is used to enable ECC on the CAN0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

can1 on page 6-84

This register is used to enable ECC on the CAN1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

nand on page 6-85

This register is used to enable ECC on the NAND RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

qspi on page 6-87

This register is used to enable ECC on the QSPI RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

sdmmc on page 6-88

This register is used to enable ECC on the SDMMC RAM. ECC errors can be injected into the write path using bits in this register. Only reset by a cold reset (ignores warm reset).

I2

This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register is reset by a cold reset (ignores warm reset). The interrupt status of the L2 ECC single/double bit error is handled in the General Interrupt Controller (GIC).

Pin Mux Control Group Register Descriptions

Controls Pin Mux selections NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

Offset: 0x400

EMACIO0 on page 6-108

This register is used to control the peripherals connected to emac0_tx_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO1 on page 6-108

This register is used to control the peripherals connected to emac0_tx_d0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO2 on page 6-109

This register is used to control the peripherals connected to emac0_tx_d1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO3 on page 6-110

This register is used to control the peripherals connected to emac0_tx_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO4 on page 6-111

This register is used to control the peripherals connected to emac0_tx_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO5 on page 6-111

This register is used to control the peripherals connected to emac0_rx_d0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO6 on page 6-112

This register is used to control the peripherals connected to `emac0_mdio` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO7 on page 6-113

This register is used to control the peripherals connected to `emac0_mdc` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO8 on page 6-114

This register is used to control the peripherals connected to `emac0_rx_ctl` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO9 on page 6-114

This register is used to control the peripherals connected to `emac0_tx_ctl` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO10 on page 6-115

This register is used to control the peripherals connected to `emac0_rx_clk` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO11 on page 6-116

This register is used to control the peripherals connected to `emac0_rx_d1` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO12 on page 6-117

This register is used to control the peripherals connected to `emac0_rx_d2` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO13 on page 6-117

This register is used to control the peripherals connected to `emac0_rx_d3` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO0 on page 6-118

This register is used to control the peripherals connected to `sdmmc_cmd` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO1 on page 6-119

This register is used to control the peripherals connected to `sdmmc_pwren` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO2 on page 6-120

This register is used to control the peripherals connected to `sdmmc_d0` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO3 on page 6-120

This register is used to control the peripherals connected to sdmmc_d1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO4 on page 6-121

This register is used to control the peripherals connected to sdmmc_d4 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO5 on page 6-122

This register is used to control the peripherals connected to sdmmc_d5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO6 on page 6-123

This register is used to control the peripherals connected to sdmmc_d6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO7 on page 6-123

This register is used to control the peripherals connected to sdmmc_d7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO8 on page 6-124

This register is used to control the peripherals connected to sdmmc_clk_in Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO9 on page 6-125

This register is used to control the peripherals connected to sdmmc_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO10 on page 6-126

This register is used to control the peripherals connected to sdmmc_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

FLASHIO11 on page 6-126

This register is used to control the peripherals connected to sdmmc_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO0 on page 6-127

This register is used to control the peripherals connected to trace_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO1 on page 6-128

This register is used to control the peripherals connected to trace_d0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO2 on page 6-129

This register is used to control the peripherals connected to trace_d1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO3 on page 6-129

This register is used to control the peripherals connected to trace_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO4 on page 6-130

This register is used to control the peripherals connected to trace_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO5 on page 6-131

This register is used to control the peripherals connected to trace_d4 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO6 on page 6-132

This register is used to control the peripherals connected to trace_d5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO7 on page 6-132

This register is used to control the peripherals connected to trace_d6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO8 on page 6-133

This register is used to control the peripherals connected to trace_d7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO9 on page 6-134

This register is used to control the peripherals connected to spim0_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO10 on page 6-135

This register is used to control the peripherals connected to spim0_mosi Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO11 on page 6-135

This register is used to control the peripherals connected to spim0_miso Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO12 on page 6-136

This register is used to control the peripherals connected to spim0_ss0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO13 on page 6-137

This register is used to control the peripherals connected to `uart0_rx` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO14 on page 6-138

This register is used to control the peripherals connected to `uart0_tx` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO15 on page 6-138

This register is used to control the peripherals connected to `i2c0_sda` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO16 on page 6-139

This register is used to control the peripherals connected to `i2c0_scl` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO17 on page 6-140

This register is used to control the peripherals connected to `can0_rx` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GENERALIO18 on page 6-141

This register is used to control the peripherals connected to `can0_tx` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO0 on page 6-141

This register is used to control the peripherals connected to `nand_ale` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO1 on page 6-142

This register is used to control the peripherals connected to `nand_ce` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO2 on page 6-143

This register is used to control the peripherals connected to `nand_cle` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO3 on page 6-144

This register is used to control the peripherals connected to `nand_re` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO4 on page 6-144

This register is used to control the peripherals connected to `nand_rb` Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO5 on page 6-145

This register is used to control the peripherals connected to nand_dq0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO6 on page 6-146

This register is used to control the peripherals connected to nand_dq1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO7 on page 6-147

This register is used to control the peripherals connected to nand_dq2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO8 on page 6-147

This register is used to control the peripherals connected to nand_dq3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO9 on page 6-148

This register is used to control the peripherals connected to nand_dq4 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO10 on page 6-149

This register is used to control the peripherals connected to nand_dq5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO11 on page 6-150

This register is used to control the peripherals connected to nand_dq6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO12 on page 6-150

This register is used to control the peripherals connected to nand_dq7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO13 on page 6-151

This register is used to control the peripherals connected to nand_wp Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO14 on page 6-152

This register is used to control the peripherals connected to nand_we Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO15 on page 6-153

This register is used to control the peripherals connected to qspi_io0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO16 on page 6-153

This register is used to control the peripherals connected to qspi_io1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO17 on page 6-154

This register is used to control the peripherals connected to qspi_io2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO18 on page 6-155

This register is used to control the peripherals connected to qspi_io3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO19 on page 6-156

This register is used to control the peripherals connected to qspi_ss0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO20 on page 6-156

This register is used to control the peripherals connected to qpsi_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

MIXED1IO21 on page 6-157

This register is used to control the peripherals connected to qspi_ss1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX48 on page 6-158

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 48. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX49 on page 6-159

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 49. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX50 on page 6-159

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 50. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX51 on page 6-160

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 51. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX52 on page 6-161

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 52. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX53 on page 6-161

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 53. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX54 on page 6-162

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 54. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX55 on page 6-163

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 55. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX56 on page 6-164

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 56. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX57 on page 6-164

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 57. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX58 on page 6-165

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 58. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX59 on page 6-166

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 59. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX60 on page 6-167

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 60. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX61 on page 6-167

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 61. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX62 on page 6-168

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 62. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX63 on page 6-169

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 63. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX64 on page 6-170

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 64. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX65 on page 6-170

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 65. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX66 on page 6-171

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 66. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX67 on page 6-172

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 67. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX68 on page 6-173

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 68. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX69 on page 6-173

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 69. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLINMUX70 on page 6-174

Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 70. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX0 on page 6-175

Selection between GPIO and LoanIO output and output enable for GPIO0 and LoanIO0. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX1 on page 6-176

Selection between GPIO and LoanIO output and output enable for GPIO1 and LoanIO1. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX2 on page 6-177

Selection between GPIO and LoanIO output and output enable for GPIO2 and LoanIO2. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX3 on page 6-177

Selection between GPIO and LoanIO output and output enable for GPIO3 and LoanIO3. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX4 on page 6-178

Selection between GPIO and LoanIO output and output enable for GPIO4 and LoanIO4. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX5 on page 6-179

Selection between GPIO and LoanIO output and output enable for GPIO5 and LoanIO5. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX6 on page 6-180

Selection between GPIO and LoanIO output and output enable for GPIO6 and LoanIO6. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX7 on page 6-181

Selection between GPIO and LoanIO output and output enable for GPIO7 and LoanIO7. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX8 on page 6-181

Selection between GPIO and LoanIO output and output enable for GPIO8 and LoanIO8. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX9 on page 6-182

Selection between GPIO and LoanIO output and output enable for GPIO9 and LoanIO9. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX10 on page 6-183

Selection between GPIO and LoanIO output and output enable for GPIO10 and LoanIO10. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX11 on page 6-184

Selection between GPIO and LoanIO output and output enable for GPIO11 and LoanIO11. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX12 on page 6-185

Selection between GPIO and LoanIO output and output enable for GPIO12 and LoanIO12. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX13 on page 6-185

Selection between GPIO and LoanIO output and output enable for GPIO13 and LoanIO13. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX14 on page 6-186

Selection between GPIO and LoanIO output and output enable for GPIO14 and LoanIO14. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX15 on page 6-187

Selection between GPIO and LoanIO output and output enable for GPIO15 and LoanIO15. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX16 on page 6-188

Selection between GPIO and LoanIO output and output enable for GPIO16 and LoanIO16. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX17 on page 6-189

Selection between GPIO and LoanIO output and output enable for GPIO17 and LoanIO17. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX18 on page 6-189

Selection between GPIO and LoanIO output and output enable for GPIO18 and LoanIO18. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX19 on page 6-190

Selection between GPIO and LoanIO output and output enable for GPIO19 and LoanIO19. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX20 on page 6-191

Selection between GPIO and LoanIO output and output enable for GPIO20 and LoanIO20. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX21 on page 6-192

Selection between GPIO and LoanIO output and output enable for GPIO21 and LoanIO21. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX22 on page 6-193

Selection between GPIO and LoanIO output and output enable for GPIO22 and LoanIO22. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX23 on page 6-193

Selection between GPIO and LoanIO output and output enable for GPIO23 and LoanIO23. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX24 on page 6-194

Selection between GPIO and LoanIO output and output enable for GPIO24 and LoanIO24. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX25 on page 6-195

Selection between GPIO and LoanIO output and output enable for GPIO25 and LoanIO25. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX26 on page 6-196

Selection between GPIO and LoanIO output and output enable for GPIO26 and LoanIO26. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX27 on page 6-197

Selection between GPIO and LoanIO output and output enable for GPIO27 and LoanIO27. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX28 on page 6-197

Selection between GPIO and LoanIO output and output enable for GPIO28 and LoanIO28. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX29 on page 6-198

Selection between GPIO and LoanIO output and output enable for GPIO29 and LoanIO29. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX30 on page 6-199

Selection between GPIO and LoanIO output and output enable for GPIO30 and LoanIO30. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX31 on page 6-200

Selection between GPIO and LoanIO output and output enable for GPIO31 and LoanIO31. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX32 on page 6-201

Selection between GPIO and LoanIO output and output enable for GPIO32 and LoanIO32. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX33 on page 6-201

Selection between GPIO and LoanIO output and output enable for GPIO33 and LoanIO33. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX34 on page 6-202

Selection between GPIO and LoanIO output and output enable for GPIO34 and LoanIO34. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX35 on page 6-203

Selection between GPIO and LoanIO output and output enable for GPIO35 and LoanIO35. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX36 on page 6-204

Selection between GPIO and LoanIO output and output enable for GPIO36 and LoanIO36. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX37 on page 6-205

Selection between GPIO and LoanIO output and output enable for GPIO37 and LoanIO37. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX38 on page 6-205

Selection between GPIO and LoanIO output and output enable for GPIO38 and LoanIO38. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX39 on page 6-206

Selection between GPIO and LoanIO output and output enable for GPIO39 and LoanIO39. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX40 on page 6-207

Selection between GPIO and LoanIO output and output enable for GPIO40 and LoanIO40. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX41 on page 6-208

Selection between GPIO and LoanIO output and output enable for GPIO41 and LoanIO41. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX42 on page 6-209

Selection between GPIO and LoanIO output and output enable for GPIO42 and LoanIO42. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX43 on page 6-209

Selection between GPIO and LoanIO output and output enable for GPIO43 and LoanIO43. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX44 on page 6-210

Selection between GPIO and LoanIO output and output enable for GPIO44 and LoanIO44. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX45 on page 6-211

Selection between GPIO and LoanIO output and output enable for GPIO45 and LoanIO45. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX46 on page 6-212

Selection between GPIO and LoanIO output and output enable for GPIO46 and LoanIO46. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX47 on page 6-213

Selection between GPIO and LoanIO output and output enable for GPIO47 and LoanIO47. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX48 on page 6-213

Selection between GPIO and LoanIO output and output enable for GPIO48 and LoanIO48. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX49 on page 6-214

Selection between GPIO and LoanIO output and output enable for GPIO49 and LoanIO49. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX50 on page 6-215

Selection between GPIO and LoanIO output and output enable for GPIO50 and LoanIO50. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX51 on page 6-216

Selection between GPIO and LoanIO output and output enable for GPIO51 and LoanIO51. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX52 on page 6-217

Selection between GPIO and LoanIO output and output enable for GPIO52 and LoanIO52. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX53 on page 6-217

Selection between GPIO and LoanIO output and output enable for GPIO53 and LoanIO53. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX54 on page 6-218

Selection between GPIO and LoanIO output and output enable for GPIO54 and LoanIO54. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX55 on page 6-219

Selection between GPIO and LoanIO output and output enable for GPIO55 and LoanIO55. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX56 on page 6-220

Selection between GPIO and LoanIO output and output enable for GPIO56 and LoanIO56. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX57 on page 6-221

Selection between GPIO and LoanIO output and output enable for GPIO57 and LoanIO57. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX58 on page 6-221

Selection between GPIO and LoanIO output and output enable for GPIO58 and LoanIO58. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX59 on page 6-222

Selection between GPIO and LoanIO output and output enable for GPIO59 and LoanIO59. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX60 on page 6-223

Selection between GPIO and LoanIO output and output enable for GPIO60 and LoanIO60. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX61 on page 6-224

Selection between GPIO and LoanIO output and output enable for GPIO61 and LoanIO61. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX62 on page 6-225

Selection between GPIO and LoanIO output and output enable for GPIO62 and LoanIO62. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX63 on page 6-225

Selection between GPIO and LoanIO output and output enable for GPIO63 and LoanIO63. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX64 on page 6-226

Selection between GPIO and LoanIO output and output enable for GPIO64 and LoanIO64. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX65 on page 6-227

Selection between GPIO and LoanIO output and output enable for GPIO65 and LoanIO65. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX66 on page 6-228

Selection between GPIO and LoanIO output and output enable for GPIO66 and LoanIO66. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX67 on page 6-229

Selection between GPIO and LoanIO output and output enable for GPIO67 and LoanIO67. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX68 on page 6-229

Selection between GPIO and LoanIO output and output enable for GPIO68 and LoanIO68. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX69 on page 6-230

Selection between GPIO and LoanIO output and output enable for GPIO69 and LoanIO69. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

GPLMUX70 on page 6-231

Selection between GPIO and LoanIO output and output enable for GPIO70 and LoanIO70. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

UART0USEFPGA on page 6-232

Selection between HPS Pins and FPGA Interface for UART0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

RGMI11USEFPGA on page 6-232

Selection between HPS Pins and FPGA Interface for RGMII1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

SPIS0USEFPGA on page 6-233

Selection between HPS Pins and FPGA Interface for SPIS0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

CAN0USEFPGA on page 6-234

Selection between HPS Pins and FPGA Interface for CAN0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

I2C0USEFPGA on page 6-235

Selection between HPS Pins and FPGA Interface for I2C0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

SDMMCUSEFPGA on page 6-235

Selection between HPS Pins and FPGA Interface for SDMMC signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections

QSPIUSEFPGA on page 6-236

Selection between HPS Pins and FPGA Interface for QSPI signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

SPIS1USEFPGA on page 6-237

Selection between HPS Pins and FPGA Interface for SPIS1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

RGMII0USEFPGA on page 6-237

Selection between HPS Pins and FPGA Interface for RGMII0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

UART1USEFPGA on page 6-238

Selection between HPS Pins and FPGA Interface for UART1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

CAN1USEFPGA on page 6-239

Selection between HPS Pins and FPGA Interface for CAN1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

I2C3USEFPGA on page 6-240

Selection between HPS Pins and FPGA Interface for I2C3 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

I2C2USEFPGA on page 6-240

Selection between HPS Pins and FPGA Interface for I2C2 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

I2C1USEFPGA on page 6-241

Selection between HPS Pins and FPGA Interface for I2C1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

SPIM1USEFPGA on page 6-242

Selection between HPS Pins and FPGA Interface for SPIM1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

SPIM0USEFPGA on page 6-242

Selection between HPS Pins and FPGA Interface for SPIM0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

EMACIO0

This register is used to control the peripherals connected to `emac0_tx_clk`. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08400

The scan manager is used to configure and manage the HPS I/O pins, and communicate with the FPGA JTAG test access port (TAP) controller. The scan manager drives the HPS I/O scan chains to configure the I/O bank properties before the pins are used by the peripherals in HPS. The scan manager can also optionally communicate with the FPGA JTAG TAP controller to send commands for purposes such as managing cyclic redundancy check (CRC) errors detected by the FPGA control block. When the scan manager communicates with the FPGA JTAG TAP controller, input on the FPGA JTAG pins is ignored.

The scan manager contains an Arm JTAG Access Port (JTAG-AP). The JTAG-AP implements a multiple scan-chain JTAG master interface. One scan chain connects to the FPGA JTAG and uses the standard JTAG signals. Four other scan chains connect to the HPS I/O banks, using the JTAG clock and data outputs as a parallel-to-serial converter.

Features of the Scan Manager

- Drives all the I/O scan chains for HPS I/O banks
- Allows the HPS to access the FPGA JTAG TAP controller

Scan Manager Block Diagram and System Integration

Figure 7-1: Scan Manager Block Diagram

(1) Not all devices contain all the banks depicted.

The processor accesses the scan manager through the register slave interface connected to the level 4 (L4) peripheral bus.

Arm JTAG-AP Signal Use in the Scan Manager

The following table describes how the Arm JTAG-AP signals are connected in the scan manager. These signals are internal to the scan manager, are provided here for reference only, and are not shown in the preceding figure. The signal, register, and field names listed in the table match the names used in the *Arm Debug Interface v5 Architecture Specification*.

Signal	Direction	Implementation
SRSTCONNECTED[7:0]	Input	Tied to 0. The read-only SRSTCONNECTED field in the CSW register always reads as 0.
PORTCONNECTED[7:0]	Input	Tied to 0x8F, which connects only ports 0-3 and 7. The read-only PORTCONNECTED field in the CSW register reads as 1 when the PORTSEL register is written with a value that enables one of the connected ports, and reads as 0 otherwise.
PORTENABLED[7:0]	Input	Tied to 0x8F, so all connected ports are always considered powered on. The Arm JTAG AP PSTA register is not supported. Software does not need to monitor the status of ports 0-3 because they are always on. For port 7, software can read the mode field of the stat register in the FPGA manager to determine the FPGA power status.
nSRSTOUT[7:0]	Output	Not connected. Writing to the SRST_OUT field of the CSW register has no effect.
nTRST*[7:0]	Output	nTRST*[7] is connected to the FPGA JTAG TAP controller and nTRST*[6:0] are not connected. Writing to the TRST_OUT field of the CSW register (the trst bit of the stat register in the scan manager) has an effect only when port 7 is enabled by software. For details, refer to “Communicating with the JTAG TAP Controller”.

Arm JTAG-AP Scan Chains

The Arm JTAG-AP supports up to eight scan chains. The scan manager uses only scan chains 0, 1, 2, 3, and 7.

Scan chain 7 of the JTAG-AP connects to FPGA JTAG TAP controller. When the system manager undergoes a cold reset, this connection is disabled and the FPGA JTAG pins are connected to the FPGA JTAG TAP controller. You can configure the system manager to enable the connection, which allows software running on the HPS to communicate with the FPGA JTAG TAP controller. In this case, software can send JTAG commands (such as the SHIFT_EDERROR_REG JTAG instruction) to the FPGA JTAG and get responses to determine details about CRC errors detected by the control block when the FPGA fabric is in user mode. Through the FPGA manager, software can determine that a CRC error was detected. For more

information about the TAP controller, refer to the *Communicating with the JTAG TAP Controller* section of this chapter.

Scan chains 0 to 3 of the JTAG-AP connect to the configuration information in the HPS I/O scan chain banks through the I/O configuration shift register (IOCSR) multiplexer. For more information, refer to the *Configuring HPS I/O Scan Chains* section of this chapter.

Note: The I/O scan chains do not use the JTAG protocol. The scan manager uses the JTAG-AP as a parallel-to-serial converter for the I/O scan chains. The I/O scan chains are connected only to the serial output data (T_{DI} JTAG signal) and serial clock (T_{CK} JTAG signal).

The HPS I/O pins are divided into six banks. Each I/O bank is either a vertical (VIO) or horizontal (HIO) I/O, based on its location on the die.

Table 7-1: Bank Usage of IOCSR Scan Chains

The following table shows the mapping of the IOCSR scan chains to the I/O banks.

IOCSR Scan Chain	Bank Type	HPS I/O Bank	Usage
0	VIO	I/O bank 7D and I/O bank 7E	EMAC
1	VIO	I/O bank 7B and I/O bank 7C	SD/MMC, NAND, and quad SPI
2	VIO	I/O bank 7A	Trace, SPI, UART, I ² C, and CAN
3	HIO	I/O bank 6	SDRAM DDR

When the FPGA JTAG TAP controller is in `CONFIG_IO` mode, the controller can override the scan manager JTAG-AP and configure the HPS I/O pins. For more information, refer to the *Configuring HPS I/O Scan Chains* section of this chapter.

Note: `CONFIG_IO` mode is commonly used to configure the I/O pin properties prior to performing boundary scan testing.

Note: The HPS JTAG pins and the following HPS I/O pins do not support boundary scan tests (BST):

- DDR SDRAM
- OSC1/2
- Warm/Cold reset

To perform boundary scan testing on HPS I/O pins, use the FPGA JTAG.

Functional Description of the Scan Manager

The scan manager serves the following purposes:

- Configuring HPS I/O scan chains
- Communicating with the JTAG TAP controller

Configuring HPS I/O Scan Chains

The HPS I/O pins are configured through a series of scan chains.

I/O pin configuration involves such steps as setting the I/O standard and drive strength for each I/O bank. After a cold reset, all the I/O scan chains in the HPS must be configured prior to being used to communicate with external devices.

Software uses the scan manager to write configuration data to the scan chains. Separate I/O configuration data files for FPGA and HPS are generated by the Quartus® Prime software when the configuration image for the FPGA portion of the system-on-a-chip (SoC) device is assembled. The HPS configuration data is written to the scan manager by software.

Before configuring a specific I/O bank, the corresponding scan chain must be enabled by writing to the bits in the `en` register. The scan manager must not be active during this process. Software reads the active bit of the `stat` register to determine the scan manager state.

Alternatively, when the FPGA JTAG TAP controller receives the `CONFIG_IO` JTAG instruction, the control block enters `CONFIG_IO` mode. When the control block is in `CONFIG_IO` mode, the controller can override the scan manager JTAG-AP and configure the HPS I/O pins. The `CONFIG_IO` instruction configures all configurable I/O pins in the SoC device including the FPGA I/O pins and the HPS I/O pins. The FPGA and HPS portions of the device must both be powered on to execute the `CONFIG_IO` instruction. External logic connected to the FPGA JTAG pins sends the `CONFIG_IO` instruction, which provides I/O configuration data for all FPGA and HPS I/O pins. While `CONFIG_IO` mode is active, the HPS is held in cold reset to prevent software from potentially interfering with the I/O configuration.

- [System Manager](#) on page 6-1
The HPS I/O pins need to be frozen before configuring them. For more information, refer to the *System Manager* chapter.

Communicating with the JTAG TAP Controller

After the system manager undergoes a cold reset, access to the JTAG TAP controller in the FPGA control block is through the dedicated FPGA JTAG I/O pins. If necessary, you can configure your system to use the scan manager to provide the HPS processor access to the JTAG TAP controller, instead. This feature allows the processor to send JTAG instructions to the FPGA portion of the device.

To connect scan chain 7 between the scan manager and the FPGA JTAG TAP controller, the following features must be enabled:

- The scan chain for the FPGA JTAG TAP controller—To enable scan chain 7, set the `fpga_jtag` field of the `en` register in the scan manager. For more information, refer to "Scan Manager Address Map and Register Definitions".
- The FPGA JTAG logic source select—This source select determines whether the scan manager or the dedicated FPGA JTAG pins are connected to the FPGA JTAG TAP controller in the FPGA portion of the device. On system manager cold reset, the dedicated FPGA JTAG pins are selected. The source select is configured through the `fpga_jtag_en` bit of the `ctrl` register in the `scanmgrgrp` group of the system manager. The FPGA JTAG pins and scan manager connection to the TAP controller must both be inactive when switching between them. The mechanism to ensure both are inactive is user-defined.

Note: Before connecting or disconnecting the scan chain between the scan manager and the FPGA JTAG TAP controller, ensure that both the FPGA JTAG `TCK` and scan manager `TCK` signals are de-asserted. Altera recommends resetting the FPGA JTAG TAP controller using the scan manager's `nTRST` signal after the scan manager is connected to the controller.

JTAG-AP FIFO Buffer Access and Byte Command Protocol

The JTAG-AP contains FIFO buffers for byte commands and responses. The buffers are accessed through the `fifosinglebyte`, `fifodoublebyte`, `fifotriplebyte`, and `fifoquadbyte` registers. The JTAG-AP stalls processor access to the registers when the buffer does not contain enough data for read access, or when the buffer does not contain enough free space to accept data for write access.

Note: Software should read the `rfifocnt` and `wfifocnt` fields of the `stat` register to determine the buffer status before performing the access to avoid being stalled by the JTAG-AP.

JTAG-AP scan chains 0, 1, 2 and 3 are write-only ports connected to the HPS IOCSRs and JTAG-AP scan chain 7 is a read-write port connected to the FPGA JTAG TAP controller. The processor can send data to scan chains 0-3, and send and receive data from scan chain 7 by accessing the command and response FIFO buffers in the JTAG-AP.

Note: Attempting to access data at invalid or non-aligned offsets can produce unpredictable results that require a reset to recover.

The JTAG commands and TDI data must be sent to the JTAG-AP using an encoded byte protocol. Similarly, the TDO data received from JTAG-AP is encoded. All commands are 8 bits wide in the byte command protocol.

Table 7-2: JTAG-AP Byte Command Protocol

Bits of the Command Byte								Opcode
7	6	5	4	3	2	1	0	
0	Opcode Payload							TMS
1	0	0	Opcode Payload					TDI_TDO
1	0	1	X	X	X	X	X	Reserved

Clocks

The scan manager is connected to the `spi_m_clk` clock generated by the clock manager.

The scan manager generates two clocks. One clock routes to the control block of the FPGA portion of the SoC device with a frequency of $s\pi i_m_c\ell k / 6$ and runs at a maximum of 33 MHz. The other clock routes to the HPS I/O scan chains with a frequency of $s\pi i_m_c\ell k / 2$ and runs at a maximum frequency of 100 MHz.

Note: The `spi_m_clk` can potentially run faster than the scan manager supports so that SPI masters can support 60 Mbps rates. When the SPI master is running faster than what is supported by the scan manager, the scan manager cannot be used and must be held in reset.

Related Information

[Clock Manager](#) on page 3-1

For more information, including minimum and maximum clock frequencies, refer to the *Clock Manager* chapter.

Resets

The reset manager provides the `scan_manager_rst_n` reset signal to the scan manager for both cold and warm resets.

Because glitches can happen on the output clocks during a warm reset, the scan manager temporarily stops generation of the JTAG-AP and I/O configuration clocks. This action ensures that a warm reset does not cause output clock glitches.

Before asserting warm reset, the reset manager sends a request to the scan manager. The scan manager stops the output clock generation and acknowledges the reset manager. The reset manager then issues the warm reset. To enable this warm reset handshake, configure the `scanmgrhsen` bit of the reset manager `ctrl` register.

JTAG-AP Register Name Cross Reference Table

To clarify how Altera uses the JTAG-AP, the Arm registers are renamed in the SoC device. The following table cross references the Arm and Altera register names.

Table 7-3: JTAG-AP Register Names

Altera Register Name	Arm Register Name
<code>stat</code>	CSW (control/status word)
<code>en</code>	PSEL
<code>fifosinglebyte</code>	BWFIFO0 for writes, BRFIFO0 for reads
<code>fifodoublebyte</code>	BWFIFO1 for writes, BRFIFO1 for reads
<code>fifotriplebyte</code>	BWFIFO2 for writes, BRFIFO2 for reads
<code>fifoquadbyte</code>	BWFIFO3 for writes, BRFIFO3 for reads

Scan Manager Module Registers Address Map

Registers in the Scan Manager module. These registers are implemented by an Arm JTAG-AP module from the Arm DAP. Some register and field names have been changed to match the usage in the Scan Manager. If modified, the corresponding names from the Arm documentation are provided. Only registers and fields that are relevant to the JTAG-AP use in the Scan Manager are listed.

Base Address: 0xFFF02000

Must have the FPGA JTAG scan-chain enabled in the EN register to take effect.	RW	0x0
Value	Description									
0x0	Don't reset FPGA JTAG.									
0x1	Reset FPGA JTAG. Must have the FPGA JTAG scan-chain enabled in the EN register to take effect.									

en

This register is used to enable one of the 5 scan-chains (0-3 and 7). Only one scan-chain must be enabled at a time. A scan-chain is enabled by writing its corresponding enable field. Software must use the System Manager to put the corresponding I/O scan-chain into the frozen state before attempting to send I/O configuration data to the I/O scan-chain. Software must only write to this register when the Scan-Chain Engine is inactive. Writing this field at any other time has unpredictable results. This means that before writing to this field, software must read the STAT register and check that the ACTIVE and WFIFOCNT fields are both zero. The name of this register in Arm documentation is PSEL.

Module Instance	Base Address	Register Address

The components of the hard processor system (HPS) communicate with one another, and with other portions of the SoC device, through the system interconnect. The system interconnect consists of the following blocks:

- The main level 3 (L3) interconnect
- The level 4 (L4) buses

The system interconnect is implemented with the Arm CoreLink* Network Interconnect (NIC-301). The NIC-301 provides a foundation for a high-performance HPS system interconnect based on the Arm Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI), Advanced High-Performance Bus (AHB), and Advanced Peripheral Bus (APB) protocols. The system interconnect implements a multilayer, nonblocking architecture that supports multiple simultaneous transactions between masters and slaves, including the Cortex-A9 microprocessor unit (MPU) subsystem. The system interconnect provides five independent L4 buses to access control and status registers (CSRs) of peripherals, managers, and memory controllers.

Features of the System Interconnect

The system interconnect supports high-throughput peripheral devices. The system interconnect has the following characteristics:

- Main internal data width of 64 bits
- Programmable master priority with single-cycle arbitration
- Full pipelining to prevent master stalls
- Programmable control for FIFO buffer transaction release
- Arm TrustZone* compliant, with additional security features configurable per master
- Multiple independent L4 buses

System Interconnect Architecture

The L3 interconnect is a partially-connected switch fabric. Not all masters can access all slaves.

Internally, the L3 interconnect is partitioned into the following subswitches:

- L3 interconnect
 - Interconnect used to transfer high-throughput 64-bit data
 - Operates at up to half the MPU main clock frequency
 - Provides masters with low-latency connectivity to AXI bridges, on-chip memories, SDRAM, and FPGA manager
- L3 master peripheral switch
 - Used to connect memory-mastering peripherals to the interconnect
 - 32-bit data width
 - Operates at up to half the interconnect clock frequency
- L3 slave peripheral switch
 - Used to provide access to level 3 and 4 slave interfaces for masters of the master peripheral and interconnects
 - 32-bit data width
 - Five independent L4 buses

The L3 master and slave peripheral switches are fully-connected crossbars. The L3 interconnect is a partially-connected crossbar. The following table shows the connectivity matrix of all the master and slave interfaces of the L3 interconnect.

Main Connectivity Matrix

The L3 master and slave peripheral switches are fully-connected crossbars. The L3 interconnect is a partially-connected crossbar. The following table shows the connectivity matrix of all the master and slave interfaces of the L3 interconnect.

⁽¹⁴⁾ For details of the masters and slaves connected to the L3 master peripheral switch and L3 master peripheral switch, refer to "Interconnect Block Diagram".

System Interconnect Address Spaces

The system interconnect supports multiple address spaces.

Each address space uses some or all of the 4 GB address range. The address spaces overlap. Depending on the configuration, different address spaces are visible in different regions for each master.

The following address spaces are available:

- The L3 address space
- The MPU address space
- The SDRAM address space

Available Address Maps

The following figure shows the default system interconnect address maps for all masters. The figure is not to scale.

Figure 8-4: Address Maps for System Interconnect Masters

Notes on Address Maps

- (1) Transactions on these addresses are directly decoded by the SCU and L2 cache.
- (2) This region can be configured to access slaves on the lightweight HPS-to-FPGA bridge, by using the `remap` register.
- (3) This region can be configured to access slaves on the HPS-to-FPGA bridge, by using the `remap` register.
- (4) The MPU accesses SDRAM through a dedicated port.
- (5) This region can be configured to access on-chip RAM, by using the `remap` register.

(6) The following peripherals can master the interconnect:

- Ethernet MACs
- USB-2 OTG controllers
- NAND controllers
- ETR
- SD/MMC controller

For the MPU master, either the boot ROM or on-chip RAM maps to address 0x0 and obscures the lowest 64 KB of SDRAM.

At boot time, the MPU does not have access to the SDRAM address space from 0x00010000 to 0x00100000. This is because the MPU's SDRAM access is controlled by the MPU L2 filter registers, which only have a granularity of 1 MB. After booting completes, the MPU can change address filtering to use the lowest 1 MB of SDRAM.

For non-MPU masters, either the on-chip RAM or the SDRAM maps to address 0x0. When mapped to address 0x0, the on-chip RAM obscures the lowest 64 KB of SDRAM for non-MPU masters.

L3 Address Space

The L3 address space is 4 GB and applies to all L3 masters except the MPU subsystem.

The L3 address space configurations contain the regions shown in the following table:

Table 8-1: L3 Address Space Regions

Description	Condition	Base Address	End Address	Size
SDRAM window (without on-chip RAM)	When <code>remap.nonmpuzero</code> ⁽¹⁵⁾ is clear	0x00000000	0xBFFFFFFF	3 GB
On-chip RAM	When <code>remap.nonmpuzero</code> ⁽¹⁵⁾ is set	0x00000000	0x0000FFFF	64 KB
SDRAM window (with on-chip RAM)	When <code>remap.nonmpuzero</code> ⁽¹⁵⁾ is set	0x00010000	0xBFFFFFFF	3145664 KB = 3 GB - 64 KB
ACP window	Always visible	0x80000000	0xBFFFFFFF	1 GB
HPS-to-FPGA	When <code>remap.hps2fpga</code> ⁽¹⁵⁾ is set. Not visible to FPGA-to-HPS bridge.	0xC0000000	0xFBFFFFFFF	960 MB

⁽¹⁵⁾ For details about the `remap` register, refer to "Bit Fields for Modifying the Memory Map"

Description	Condition	Base Address	End Address	Size
System trace macrocell	Always visible to DMA and FPGA-to-HPS	0xFC000000	0xFEFFFFFF	48 KB
Debug access port	Not visible to master peripherals. Always visible to other masters.	0xFF000000	0xFF1FFFFFF	2 MB
Lightweight HPS-to-FPGA	Not visible to master peripherals. Visible to other masters when <code>remap.hps2fpga⁽¹⁵⁾</code> is set.	0xFF200000	0xFF3FFFFFF	2 MB
Peripherals	Not visible to master peripherals. Always visible to other masters.	0xFF400000	0xFFCFFFFF	12096 KB
On-chip RAM	Always visible	0xFFFF0000	0xFFFFFFFF	64 KB

The boot ROM and internal MPU registers (SCU and L2) are not accessible to L3 masters.

SDRAM Window Region

The SDRAM window region is 3 GB and provides access to the bottom 3 GB of the SDRAM address space. Any L3 master can access a cache-coherent view of SDRAM by performing a cacheable access through the ACP.

On-Chip RAM Region

The system interconnect `remap` register, in the `l3regs` group, determines if the 64 KB starting at address 0x0 is mapped to the on-chip RAM or the SDRAM. The SDRAM is mapped to address 0x0 on reset.

ACP Window Region

The ACP window region is 1 GB and provides access to a configurable gigabyte-aligned region of the MPU address space. Registers in the ACP ID mapper control which gigabyte-aligned region of the MPU address space is accessed by the ACP window region. The ACP window region is used by L3 masters to perform coherent accesses into the MPU address space. For more information about the ACP ID mapper, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to 960 MB of slaves in the FPGA fabric through the HPS-to-FPGA bridge.

Lightweight HPS-to-FPGA Slaves Region

The lightweight HPS-to-FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region includes slaves connected to the L3 interconnect and L4 buses.

On-Chip RAM Region

The on-chip RAM is always mapped (independent of the boot region contents).

Related Information

- For general information about the MPU subsystem, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

MPU Address Space

The MPU address space is 4 GB and applies to MPU masters.

Addresses generated by the MPU are decoded in three ways:

- By default, MPU accesses to locations between 0x100000 (1 MB) to 0xC0000000 (3 GB) are made to the SDRAM controller.
- Addresses in the SCU and L2 register region (0xFFFE0000 to 0xFFFF0000) are the SCU and L2 bus.
- Accesses to all other locations are made to the L3 interconnect.

The MPU L2 cache controller contains a master connected to the system interconnect and a master connected to the SDRAM.

The MPU address space contains the following regions:

Table 8-2: MPU Default Address Space Regions

Description	Condition	Base Address	End Address	Size
Boot ROM	Always visible	0x00000000	0x000FFFFFFF	1 MB
SDRAM window	Always visible	0x00100000	0xBFFFFFFF	3047 MB (3 GB – 1 MB)
HPS-to-FPGA	When <code>remap.hps2fpga⁽¹⁶⁾</code> is set.	0xC0000000	0xFBFFFFFFF	348 KB
System trace macrocell	Always visible	0xFC000000	0xFFEFFFFFFF	48 KB
Debug access port	Always visible	0xFF000000	0xFF1FFFFFFF	2 MB
Lightweight HPS-to-FPGA	Visible when <code>remap.hps2fpga⁽¹⁶⁾</code> is set.	0xFF200000	0xFF3FFFFFFF	2 MB
Peripherals	Always visible	0xFF400000	0xFFFCFFFF	12096 KB
Boot ROM	Always visible	0xFFFD0000	0xFFFEBFFF	112 KB

⁽¹⁶⁾ For details about the `remap` register, refer to "Bit Fields for Modifying the Memory Map"

Description	Condition	Base Address	End Address	Size
SCU and L2 registers	Always visible	0xFFFE0000	0xFFFF0000	16 KB
On-chip RAM	Always visible	0xFFFF0000	0xFFFFFFFF	64 KB

Boot Region

The boot region is 1 MB, based at address 0x0. The boot region is visible to the MPU only when the L2 address filter start register is set to 0x100000. The L3 `remap` control register determines if the boot region is mapped to the on-chip RAM or the boot ROM.

The boot region is mapped to the boot ROM on reset. Only the lowest 64 KB of the boot region are legal addresses because the on-chip RAM and boot ROM are only 64 KB.

When the L2 address filter start register is set to 0, SDRAM obscures access to the boot region. This technique can be used to gain access to the lowest SDRAM addresses after booting completes.

SDRAM Window Region

The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space. The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries.

The boundaries are megabyte-aligned. Addresses within the boundaries map to the SDRAM controller, which queues the read and write transactions for execution. Addresses that fall outside the boundaries route to the system interconnect, to access peripherals, bridges, and other HPS resources.

Addresses in the SDRAM window match addresses in the SDRAM address space. Thus, the lowest 1 MB of the SDRAM is not visible to the MPU unless the L2 address filter start register is set to 0.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to slaves in the FPGA fabric through the HPS-to-FPGA bridge. Software can move the top of the SDRAM window by writing to the L2 address filter end register. If higher addresses are made available in the SDRAM window, part of the FPGA slaves region might be inaccessible to the MPU.

Lightweight HPS-to-FPGA Slaves Region

The lightweight FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region is near the top of the address space. The peripheral region includes slaves connected to the L3 interconnect and L4 buses.

Boot ROM Region

The boot ROM is always mapped near the top of the address space, independent of the boot region contents.

SCU and L2 Registers Region

The SCU and L2 registers region provides access to internally-decoded MPU registers (SCU and L2).

On-Chip RAM Region

The on-chip RAM is always mapped near the top of the address space, independent of the boot region contents.

SDRAM Address Space

The SDRAM address space is 4 GB. Depending on register settings, portions of it are visible to all masters.

Related Information

[HPS Address Spaces](#) on page 2-15
Figure showing the SDRAM window boundaries at reset

Address Remapping

The system interconnect supports address remapping through the `remap` register in the `l3regs` group. Remapping allows software to control which memory device (SDRAM, on-chip RAM, or boot ROM) is accessible at address 0x0 and the accessibility of the HPS-to-FPGA and lightweight HPS-to-FPGA bridges. The `remap` register is one of the NIC-301 Global Programmers View (GPV) registers. The following L3 masters can manipulate `remap`, because it maps into their address space:

- MPU
- FPGA-to-HPS bridge
- DAP

The remapping bits in the `remap` register are not mutually exclusive. The lowest order remap bit has higher priority when multiple slaves are remapped to the same address. Each bit allows different combinations of address maps to be formed. There is only one remapping register available in the GPV, so modifying the `remap` register affects all memory maps of all the masters of the system interconnect.

The effects of the remap bits can be categorized in the following groups:

- MPU master interface
 - L2 cache master 0 interface
- Non-MPU master interfaces
 - DMA master interface
 - Master peripheral interfaces
 - Debug Access Port (DAP) master interface
 - FPGA-to-HPS bridge master interface

Note: L2 filter registers in the MPU subsystem, not the interconnect, allow the SDRAM to be remapped to address 0x0 for the MPU.

Master Caching and Buffering Overrides

Some of the peripheral masters connected to the system interconnect do not have the ability to drive the caching and buffering signals of their interfaces. The system manager provides registers so that you can enable cacheable and bufferable transactions for these masters. The system manager drives the caching and buffering signals of the following masters:

Master Peripheral	System Manager Register Group	Register
EMAC0 and EMAC1	emacgrp	l3master
USB OTG 0 and USB OTG 1	usbgrp	l3master
NAND flash	nandgrp	l3master
SD/MMC	sdmmcgrp	l3master

At reset time, the system manager drives the cache and buffering signals for these masters low. In other words, the masters listed do not support cacheable or bufferable accesses until you enable them after reset. There is no synchronization between the system manager and the system interconnect, so avoid changing these settings when any of the masters are active.

Related Information

[System Manager](#) on page 6-1

For more information about enabling or disabling these features, refer to the *System Manager* chapter.

Security

Slave Security

The interconnect enforces security through the slave settings. The slave settings are controlled by the address region control registers accessible through the GPV registers. Each L3 and L4 slave has its own security check and programmable security settings. After reset, every slave of the interconnect is set to a secure state (referred to as boot secure). The only accesses allowed to secure slaves are by secure masters.

The GPV can only be accessed by secure masters. The security state of the interconnect is not accessible through the GPV as the security registers are write-only. Any nonsecure accesses to the GPV receive a `DECERR` response, and no register access is provided. Updates to the security settings through the GPV do not take effect until all transactions to the affected slave have completed.

Master Security

Masters of the system interconnect are either secure, nonsecure, or the security is set on a per transaction basis. The DAP and Ethernet masters only perform secure accesses. The L2 cache master 0, FPGA-to-HPS-bridge, and DMA perform secure and nonsecure accesses on a per transaction basis. All other system interconnect masters perform nonsecure accesses.

Accesses to secure slaves by unsecure masters result in a response of `DECERR` and the transaction does not reach the slave.

All masters are secure at reset.

Related Information

[System Interconnect Master Properties](#) on page 8-15

Configuring the Quality of Service Logic

You can programmatically configure the QoS generator for each master through the QoS registers.

Note: Before accessing the registers for any QoS generator, you must ensure that the corresponding peripheral is not in reset. Otherwise, the register access results in a bus error, causing a CPU fault.

Related Information

[L3 \(NIC-301\) GPV Registers Address Map](#) on page 8-22

Information about the GPV `write_qos` registers

Cyclic Dependency Avoidance Schemes

The AXI protocol permits re-ordering of transactions. As a result, when routing concurrent multiple transactions from a single point of divergence to multiple slaves, the interconnect might need to enforce rules to prevent deadlock.

Each master of the interconnect is configured with one of three possible cyclic dependency avoidance schemes (CDAS). The same CDAS scheme is configured for both read and write transactions, but they operate independently.

[Single Slave](#) on page 8-15

[Single Slave Per ID](#) on page 8-15

[Single Active Slave](#) on page 8-15

Related Information

[System Interconnect Master Properties](#) on page 8-15

Contains descriptions of the CDAS implementation for the masters.

Single Slave

Single slave (SS) ensures the following conditions at a slave interface of a switch:

- All outstanding read transactions are to a single end destination.
- All outstanding write transactions are to a single end destination.

If a master issues another transaction to a different destination than the current destination for that transaction type (read or write), the network stalls the transactions until all the outstanding transactions of that type have completed.

Single Slave Per ID

Single slave per ID (SSPID) ensures the following conditions at a slave interface of a switch:

- All outstanding read transactions with the same ID go the same destination.
- All outstanding write transactions with the same ID go the same destination.

When a master issues a transaction, the following situations can occur:

- If the transaction has an ID that does not match any outstanding transactions, it passes the CDAS.
- If the transaction has an ID that matches the ID of an outstanding transaction, and the destinations also match, it passes the CDAS.
- If the transaction has an ID that matches the ID of an outstanding transaction, and the destinations do not match, the transaction fails the CDAS check and stalls.

Single Active Slave

Single active slave (SAS) is the same as the SSPID scheme, with an added check for write transactions. SAS ensures that a master cannot issue a new write address until all of the data from the previous write transaction has been sent.

System Interconnect Master Properties

The system interconnect connects to various slave interfaces through the L3 interconnect and L3 slave peripheral switch.

Table 8-4: System Interconnect Master Interfaces

TrustZone security:

- Secure: All transactions are marked TrustZone secure
- Nonsecure: All transactions are marked TrustZone non-secure
- Per transaction: Transactions can be marked TrustZone secure or TrustZone non-secure, depending on the state of the system interconnect master.

Issuance is based on the number of read, write, and total transactions.

The FIFO buffer depth for AXI is based on the AW, AR, R, W, and B channels. For AHB and APB, the depth is based on W, A, and D channels.

Master	Width	Clock	Switch	TrustZone Security	GPV Access	CDAS	Issuance	FIFO Buffer Depth ⁽¹⁷⁾	Type
L2 cache M0	64	mpu_l2_ram_clk	L3 interconnect	Per Transaction	Yes	SSPID	7, 12, 19	2, 2, 2, 2, 2	AXI
FPGA-to-HPS bridge	64	l3_main_clk	L3 interconnect	Per Transaction	Yes	SAS	16, 16, 32	2, 2, 6, 6, 2	AXI
DMA	64	l4_main_clk	L3 interconnect	Per Transaction	No	SSPID	8, 8, 8	2, 2, 2, 2, 2	AXI
EMAC 0/1	32	l4_main_clk	L3 master peripheral switch	Secure	No	SSPID	16, 16, 32	2, 2, 2, 2, 2	AXI
USB OTG 0/1	32	usb_mp_clk	L3 master peripheral switch	Nonsecure	No	SSPID	2, 2, 4	2, 2, 2	AHB
NAND	32	nand_x_clk	L3 master peripheral switch	Nonsecure	No	SSPID	1, 8, 9	2, 2, 2, 2, 2	AXI
SD/MMC	32	l4_mp_clk	L3 master peripheral switch	Nonsecure	No	SSPID	2, 2, 4	2, 2, 2	AHB
ETR	32	dbg_at_clk	L3 master peripheral switch	Per Transaction	No	SSPID	32, 1, 32	2, 2, 2, 2, 2	AXI
DAP	32	dbg_clk	L3 interconnect	Secure	Yes	SS	1, 1, 1	2, 2, 2	AHB

The AXI IDs of the HPS peripheral masters identify transactions from the HPS to soft logic over the HPS-to-FPGA bridge. Soft logic in the FPGA can monitor the AXI IDs to determine which master issued each transaction. For HPS peripheral AXI IDs, refer to "HPS Peripheral Master Input IDs".

⁽¹⁷⁾ Each channel has a dedicated FIFO buffer. This allows the channels to function as independent streams.

Related Information

[HPS Peripheral Master Input IDs](#) on page 10-35

For a list of HPS peripheral AXI IDs, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

Interconnect Slave Properties

The interconnect connects to various slave interfaces through the L3 interconnect, L3 slave peripheral switch, and the five L4 peripheral buses. After reset, all slave interfaces are set to the secure state.

The interconnect provides FIFO buffers with clock crossing adapters. Refer to "FIFO Buffers and Clock Crossing" for details.

Table 8-5: Interconnect Slave Interfaces

Related Information

[FIFO Buffers and Clock Crossing](#) on page 8-21

Upsizing Data Width Function

The upsizing function combines narrow transactions into wider transactions to increase the overall system bandwidth. Upsizing only packs data for read or write transactions that are cacheable. If the interconnect

⁽¹⁸⁾ Acceptance is based on the number of read, write, and total transactions.

⁽¹⁹⁾ The FIFO buffer depth for AXI is based on the AW, AR, R, W, and B channels. For AHB and APB, the depth is based on W, A, and D channels.

splits input-exclusive transactions into more than one output bus transaction, it removes the exclusive information from the multiple transactions it creates.

The upsizing function can expand the data width by the following ratios:

- 1:2
- 1:4

If multiple responses from created transactions are combined into one response, then the following order of priority applies:

- `DECERR` is the highest priority
- `SLVERR` is the next highest priority
- `OKAY` is the lowest priority.

Incrementing Bursts

The interconnect converts all input `INCR` bursts that complete within a single output data width to an `INCR1` burst of the minimum `SIZE` possible, and packs all `INCR` bursts into `INCR` bursts of the optimal size possible for maximum data throughput.

Wrapping Bursts

All `WRAP` bursts are either passed through unconverted as `WRAP` bursts, or converted to one or two `INCR` bursts of the output bus. The interconnect converts input `WRAP` bursts that have a total payload less than the output data width to a single `INCR` burst.

Fixed Bursts

All `FIXED` bursts pass through unconverted.

Bypass Merge

Bypass merge is accessible through the GPV registers and is only accessible to secure masters. If the programmable bit `bypass_merge` is enabled, the interconnect does not alter any transactions that could pass through legally without alteration.

Downsizing Data Width Function

The downsizing function reduces the data width of a transaction to match the optimal data width at the destination. Downsizing does not merge multiple-transaction data narrower than the destination bus if the transactions are marked as noncacheable.

The downsizing function reduces the data width by the following ratios:

- 2:1
- 4:1

Incrementing Bursts

The interconnect converts `INCR` bursts that fall within the maximum payload size of the output data bus to a single `INCR` burst. It converts `INCR` bursts that are greater than the maximum payload size of the output data bus to multiple `INCR` bursts.

INCR bursts with a size that matches the output data width pass through unconverted.

The interconnect packs INCR bursts with a SIZE smaller than the output data width to match the output width whenever possible, using the upsizing function.

Related Information

[Upsizing Data Width Function](#) on page 8-19

For more information about AXI terms such as DECERR, WRAP, and INCR, refer to the *AMBA AXI Protocol Specification v1.0*, which you can download from the Arm website.

Wrapping Bursts

The interconnect always converts WRAP bursts to WRAP bursts of twice the length, up to the output data width maximum size of WRAP16, and treats the WRAP burst as two INCR bursts that can each be converted into one or more INCR bursts.

Fixed Bursts

The interconnect converts FIXED bursts to one or more INCR1 or INCRn bursts depending on the downsize ratio.

Bypass Merge

Bypass merge is accessible through the GPV registers and is only accessible to secure masters. If the programmable bit `bypass_merge` in the `fn_mod2` register is enabled, the interconnect does not perform any packing of beats to match the optimal size for maximum throughput, up to the output data width size.

If an exclusive transaction is split into multiple transactions at the output of the downsizing function, the exclusive flag is removed and the master never receives an EXOKAY response. Response priority is the same as for the upsizing function.

Related Information

- [fn_mod2](#) on page 8-98
 - [Upsizing Data Width Function](#) on page 8-19
- For more information about AXI terms such as DECERR, WRAP, and INCR, refer to the *AMBA AXI Protocol Specification v1.0*, which you can download from the Arm website.

Lock Support

Lock is not supported by the interconnect. For atomic accesses, masters can perform exclusive accesses when sharing data located in the HPS SDRAM.

Related Information

[SDRAM Controller Subsystem](#) on page 12-1

For more information about exclusive access support, refer to the *SDRAM Controller Subsystem* chapter.

FIFO Buffers and Clock Crossing

The interconnect provides FIFO buffers in the following locations:

- On interfaces to all HPS master and slaves except onchip RAM and boot ROM
- Between subswitches

In addition to buffering, these FIFOs also provide clock domain crossing where masters and slaves operate at a different clock frequency from the switch they connect to.

Data Release Mechanism

For system interconnect ports with data FIFO buffers whose depth is greater than zero, you can set a write tidemark function, `wr_tidemark`. This tidemark level stalls the release of the transaction until one of the following situations occurs:

- The system interconnect receives the `wLAST` beat of a burst.
- The write data FIFO buffer becomes full.
- The number of occupied slots in the write data FIFO buffer exceeds the write tidemark.

Related Information

remap

The L3 interconnect has separate address maps for the various L3 Masters. Generally, the addresses are the same for most masters. However, the sparse interconnect of the L3 switch causes some masters to have holes in their memory maps. The remap bits are not mutually exclusive. Each bit can be set independently

and in combinations. Priority for the bits is determined by the bit offset: lower offset bits take precedence over higher offset bits.

Module Instance	Base Address	Register Address
l3regs	0xFF800000	0xFF800000

Offset: 0x0

Access: WO

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

0x0	Maps the Boot ROM to address 0x0 for the MPU L3 master. Note that the Boot ROM is also always mapped to address 0xfffd_0000 for the MPU L3 master independent of this field's value.									
0x1	Maps the On-chip RAM to address 0x0 for the MPU L3 master. Note that the On-chip RAM is also always mapped to address 0xffff_0000 for the MPU L3 master independent of this field's value.									

Security Register Group Register Descriptions

Registers that control slave security.

Offset: 0x8

l4main on page 8-34

Controls security settings for L4 main peripherals

l4sp on page 8-36

Controls security settings for L4 SP peripherals.

l4mp on page 8-39

Controls security settings for L4 MP peripherals.

l4osc1 on page 8-42

Controls security settings for L4 OSC1 peripherals.

l4spim on page 8-44

Controls security settings for L4 SPIM peripherals.

stm on page 8-46

Controls security settings for STM peripheral.

lwhps2fpgaregs on page 8-47

Controls security settings for LWHPS2FPGA AXI Bridge Registers peripheral.

usb1 on page 8-48

Controls security settings for USB1 Registers peripheral.

nanddata on page 8-49

Controls security settings for NAND Flash Controller Data peripheral.

usb0 on page 8-50

Controls security settings for USB0 Registers peripheral.

nandregs on page 8-51

Controls security settings for NAND Flash Controller Registers peripheral.

qspidata on page 8-52

Controls security settings for QSPI Flash Controller Data peripheral.

fpgamgrdata on page 8-53

Controls security settings for FPGA Manager Data peripheral.

hps2fpgaregs on page 8-54

Controls security settings for HPS2FPGA AXI Bridge Registers peripheral.

acp on page 8-55

Controls security settings for MPU ACP peripheral.

rom on page 8-56

Controls security settings for ROM peripheral.

ocram on page 8-57

Controls security settings for On-chip RAM peripheral.

sdrdata on page 8-58

Controls security settings for SDRAM Data peripheral.

l4main

Controls security settings for L4 main peripherals

EMAC1 Register Descriptions

Registers associated with the EMAC1 slave interface. This slave is used by the DMA controller built into the EMAC1 to access slaves attached to the L3/L4 Interconnect.

Offset: 0x7000

read_qos on page 8-120

QoS (Quality of Service) value for the read channel.

write_qos on page 8-120

QoS (Quality of Service) value for the write channel.

fn_mod on page 8-121

Sets the block issuing capability to multiple or single outstanding transactions.

read_qos

QoS (Quality of Service) value for the read channel.

Module Instance	Base Address	Register Address
13regs	0xFF800000	0xFF849100

Offset: 0x49100

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

This chapter describes the bridges in the hard processor system (HPS) used to communicate data between the FPGA fabric and HPS logic. The bridges use the Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) protocol, and are based on the AMBA Network Interconnect (NIC-301).

The HPS contains the following HPS-FPGA bridges:

- FPGA-to-HPS Bridge
- HPS-to-FPGA Bridge
- Lightweight HPS-to-FPGA Bridge

Related Information

- [Functional Description of the FPGA-to-HPS Bridge](#) on page 9-4
- [HPS-to-FPGA Bridge Clocks and Resets](#) on page 9-55
- [Lightweight HPS-to-FPGA Bridge Clocks and Resets](#) on page 9-55

Features of the HPS-FPGA Bridges

The HPS-FPGA bridges allow masters in the FPGA fabric to communicate with slaves in the HPS logic and vice versa. For example, if you implement memories or peripherals in the FPGA fabric, HPS components such as the MPU can access them. Components implemented in the FPGA fabric, such as the Nios[®] II processor, can also access memories and peripherals in the HPS logic.

Table 9-1: HPS-FPGA Bridge Features

Feature	FPGA-to-HPS Bridge	HPS-to-FPGA Bridge	Lightweight HPS-to-FPGA Bridge
Supports the AMBA AXI3 interface protocol	Y	Y	Y
Implements clock crossing and manages the transfer of data across the clock domains in the HPS logic and the FPGA fabric	Y	Y	Y

Feature	FPGA-to-HPS Bridge	HPS-to-FPGA Bridge	Lightweight HPS-to-FPGA Bridge
Performs data width conversion between the HPS logic and the FPGA fabric	Y	Y	Y
Allows configuration of FPGA interface widths at instantiation time	Y	Y	N

Each bridge consists of a master-slave pair with one interface exposed to the FPGA fabric and the other exposed to the HPS logic. The FPGA-to-HPS bridge exposes an AXI slave interface that you can connect to AXI master or Avalon-MM interfaces in the FPGA fabric. The HPS-to-FPGA and lightweight HPS-to-FPGA bridges expose an AXI master interface that you can connect to AXI or Avalon-MM slave interfaces in the FPGA fabric.

[AXI Bridges](#) on page 28-7

Information about configuring the AXI bridges

HPS-FPGA Bridges Block Diagram and System Integration

Figure 9-1: HPS-FPGA Bridge Connectivity

The following figure shows the HPS-FPGA bridges in the context of the FPGA fabric and the L3 interconnect to the HPS. Each master (M) and slave (S) interface is shown with its data width(s). The clock domain for each interconnect is shown in parentheses.

The HPS-to-FPGA bridge is mastered by the level 3 (L3) main switch and the lightweight HPS-to-FPGA bridge is mastered by the L3 slave peripheral switch.

The FPGA-to-HPS bridge masters the L3 main switch, allowing any master implemented in the FPGA fabric to access most slaves in the HPS. For example, the FPGA-to-HPS bridge can access the accelerator coherency port (ACP) of the Cortex-A9 MPU subsystem to perform cache-coherent accesses to the SDRAM subsystem.

All three bridges contain global programmers view (GPV) registers. The GPV registers control the behavior of the bridge. Access to the GPV registers of all three bridges is provided through the lightweight HPS-to-FPGA bridge.

Related Information

- [Clocks and Resets](#) on page 9-54
- [Functional Description of the System Interconnect](#)
Detailed information about connectivity, such as which masters have access to each bridge

Functional Description of the HPS-FPGA Bridges

The Global Programmers View

The HPS-to-FPGA bridge includes a set of registers called the GPV. The GPV provides settings to control the bridge properties and behavior. Access to the GPV registers of all three bridges is provided through the lightweight HPS-to-FPGA bridge.

The GPV registers can only be accessed by secure masters in the HPS or the FPGA fabric.

Functional Description of the FPGA-to-HPS Bridge

The FPGA-to-HPS bridge provides access to the peripherals and memory in the HPS. This access is available to any master implemented in the FPGA fabric. You can configure the bridge slave, which is exposed to the FPGA fabric, to support 32-, 64-, or 128-bit data. The master interface of the bridge, connected to the L3 interconnect, has a data width of 64 bits.

Table 9-2: FPGA-to-HPS Bridge Properties

The following table lists the properties of the FPGA-to-HPS bridge, including the configurable slave interface exposed to the FPGA fabric.

Bridge Property	FPGA Slave Interface	L3 Master Interface
Data width ⁽²⁰⁾	32, 64, or 128 bits	64 bits
Clock domain	f2h_axi_clk	l3_main_clk
Byte address width	32 bits	32 bits
ID width	8 bits	8 bits
Read acceptance	16 transactions	16 transactions
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

The FPGA-to-HPS bridge address map contains a GPV. The GPV registers provide settings that adjust the bridge slave properties when the FPGA slave interface is configured to be 32 or 128 bits wide. The slave issuing capability can be adjusted, through the `fn_mod` register, to allow one or multiple transactions to be outstanding in the HPS. The slave bypass merge feature can also be enabled, through the `bypass_merge` bit in the `fn_mod2` register. This feature ensures that the upsizing and downsizing logic does not alter any transactions when the FPGA slave interface is configured to be 32 or 128 bits wide.

Note: It is critical to provide the correct `l4_mp_clk` clock to support access to the GPV, as described in "GPV Clocks".

⁽²⁰⁾ The bridge slave data width is user-configurable at the time you instantiate the HPS component in your system.

FPGA-to-HPS Access to ACP

When the error correction code (ECC) option is enabled in the level 2 (L2) cache controller, all accesses from the FPGA-to-HPS bridge to the ACP must be 64 bits wide and aligned on 8-byte boundaries after up- or downsizing takes place. Ensure that the address alignment is a multiple of 8 bytes and that (burst size) × (burst length) is a multiple of 8 bytes.

FPGA-to-HPS Bridge Slave Signals

The FPGA-to-HPS bridge slave address channels support user-sideband signals, routed to the ACP in the MPU subsystem. All the signals have a fixed width except the data and write strobes for the read and write data channels. The variable width signals depend on the data width setting of the bridge.

The following tables list all the signals exposed by the FPGA-to-HPS slave interface to the FPGA fabric.

Table 9-3: FPGA-to-HPS Bridge Slave Write Address Channel Signals

Signal	Width	Direction	Description
AWID	8 bits	Input	Write address ID
AWADDR	32 bits	Input	Write address
AWLEN	4 bits	Input	Burst length
AWSIZE	3 bits	Input	Burst size
AWBURST	2 bits	Input	Burst type
AWLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Input	Cache policy type
AWPROT	3 bits	Input	Protection type
AWVALID	1 bit	Input	Write address channel valid
AWREADY	1 bit	Output	Write address channel ready
AWUSER	5 bits	Input	User sideband signals

Table 9-4: FPGA-to-HPS Bridge Slave Write Data Channel Signals

Signal	Width	Direction	Description
WID	8 bits	Input	Write ID

Signal	Width	Direction	Description
WDATA	32, 64, or 128 bits	Input	Write data
WSTRB	4, 8, or 16 bits	Input	Write data strobes
WLAST	1 bit	Input	Write last data identifier
WVALID	1 bit	Input	Write data channel valid
WREADY	1 bit	Output	Write data channel ready

Table 9-5: FPGA-to-HPS Bridge Slave Write Response Channel Signals

Signal	Width	Direction	Description
BID	8 bits	Output	Write response ID
BRESP	2 bits	Output	Write response
BVALID	1 bit	Output	Write response channel valid
BREADY	1 bit	Input	Write response channel ready

Table 9-6: FPGA-to-HPS Bridge Slave Read Address Channel Signals

Signal	Width	Direction	Description
ARID	8 bits	Input	Read address ID
ARADDR	32 bits	Input	Read address
ARLEN	4 bits	Input	Burst length
ARSIZE	3 bits	Input	Burst size
ARBURST	2 bits	Input	Burst type
ARLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
ARCACHE	4 bits	Input	Cache policy type
ARPROT	3 bits	Input	Protection type
ARVALID	1 bit	Input	Read address channel valid
ARREADY	1 bit	Output	Read address channel ready

Signal	Width	Direction	Description
ARUSER	5 bits	Input	Read user sideband signals

Table 9-7: FPGA-to-HPS Bridge Slave Read Data Channel Signals

Signal	Width	Direction	Description
RID	8 bits	Output	Read ID
RDATA	32, 64, or 128 bits	Output	Read data
RRESP	2 bits	Output	Read response
RLAST	1 bit	Output	Read last data identifier
RVALID	1 bit	Output	Read data channel valid
RREADY	1 bit	Input	Read data channel ready

Functional Description of the HPS-to-FPGA Bridge

The HPS-to-FPGA bridge provides a configurable-width, high-performance master interface to the FPGA fabric. The bridge provides most masters in the HPS with access to logic, peripherals, and memory implemented in the FPGA. The effective size of the address space is 0x3FFF0000, or 1 gigabyte (GB) minus the 64 megabytes (MB) occupied by peripherals, lightweight HPS-to-FPGA bridge, on-chip RAM, and boot ROM in the HPS. You can configure the bridge master exposed to the FPGA fabric for 32-, 64-, or 128-bit data. The amount of address space exposed to the MPU subsystem can also be reduced through the L2 cache address filtering mechanism.

The slave interface of the bridge in the HPS logic has a data width of 64 bits. The bridge provides width adaptation and clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

Note: The HPS-to-FPGA bridge is accessed if the MPU boots from the FPGA. Before the MPU boots from the FPGA, the FPGA portion of the SoC device must be configured, and the HPS-to-FPGA bridge must be remapped into addressable space.

Table 9-8: HPS-to-FPGA Bridge Properties

The following table lists the properties of the HPS-to-FPGA bridge, including the configurable master interface exposed to the FPGA fabric.

Bridge Property	L3 Slave Interface	FPGA Master Interface
Data width ⁽²¹⁾	64 bits	32, 64, or 128 bits
Clock domain	l3_main_clk	h2f_axi_clk
Byte address width	32 bits	30 bits
ID width	12 bits	12 bits
Read acceptance	16 transactions	16 transactions
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

⁽²¹⁾ The bridge master data width is user-configurable at the time you instantiate the HPS component in your system.

The HPS-to-FPGA bridge's GPV, described in "The Global Programmers View", provides settings to adjust the bridge master properties. The master issuing capability can be adjusted, through the `fn_mod` register, to allow one or multiple transactions to be outstanding in the FPGA fabric. The master bypass merge feature can also be enabled, through the `bypass_merge` bit in the `fn_mod2` register. This feature ensures that the upsizing and downsizing logic does not alter any transactions when the FPGA master interface is configured to be 32 or 128 bits wide.

Note: It is critical to provide the correct `l4_mp_clk` clock to support access to the GPV, as described in "GPV Clocks".

HPS-to-FPGA Bridge Master Signals

All the HPS-to-FPGA bridge master signals have a fixed width except the data and write strobes for the read and write data channels. The variable-width signals depend on the data width setting of the bridge interface exposed to the FPGA logic.

The following tables list all the signals exposed by the HPS-to-FPGA master interface to the FPGA fabric.

Table 9-9: HPS-to-FPGA Bridge Master Write Address Channel Signals

Signal	Width	Direction	Description
AWID	12 bits	Output	Write address ID
AWADDR	30 bits	Output	Write address
AWLEN	4 bits	Output	Burst length
AWSIZE	3 bits	Output	Burst size
AWBURST	2 bits	Output	Burst type
AWLOCK	2 bits	Output	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Output	Cache policy type
AWPROT	3 bits	Output	Protection type
AWVALID	1 bit	Output	Write address channel valid

Signal	Width	Direction	Description
AWREADY	1 bit	Input	Write address channel ready

Table 9-10: HPS-to-FPGA Bridge Master Write Data Channel Signals

Signal	Width	Direction	Description
WID	12 bits	Output	Write ID
WDATA	32, 64, or 128 bits	Output	Write data
WSTRB	4, 8, or 16 bits	Output	Write data strobes
WLAST	1 bit	Output	Write last data identifier
WVALID	1 bit	Output	Write data channel valid
WREADY	1 bit	Input	Write data channel ready

Table 9-11: HPS-to-FPGA Bridge Master Write Response Channel Signals

Signal	Width	Direction	Description
BID	12 bits	Input	Write response ID
BRESP	2 bits	Input	Write response
BVALID	1 bit	Input	Write response channel valid
BREADY	1 bit	Output	Write response channel ready

Table 9-12: HPS-to-FPGA Bridge Master Read Address Channel Signals

Signal	Width	Direction	Description
ARID	12 bits	Output	Read address ID
ARADDR	30 bits	Output	Read address
ARLEN	4 bits	Output	Burst length
ARSIZE	3 bits	Output	Burst size
ARBURST	2 bits	Output	Burst type
ARLOCK	2 bits	Output	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)

Signal	Width	Direction	Description
ARCACHE	4 bits	Output	Cache policy type
ARPROT	3 bits	Output	Protection type
ARVALID	1 bit	Output	Read address channel valid
ARREADY	1 bit	Input	Read address channel ready

Table 9-13: HPS-to-FPGA Bridge Master Read Data Channel Signals

Signal	Width	Direction	Description
RID	12 bits	Input	Read ID
RDATA	32, 64, or 128 bits	Input	Read data
RRESP	2 bits	Input	Read response
RLAST	1 bit	Input	Read last data identifier
RVALID	1 bit	Input	Read data channel valid
RREADY	1 bit	Output	Read data channel ready

Functional Description of the Lightweight HPS-to-FPGA Bridge

The lightweight HPS-to-FPGA bridge provides a lower-performance interface to the FPGA fabric. This interface is useful for accessing the control and status registers of soft peripherals. The bridge provides a 2 MB address space and access to logic, peripherals, and memory implemented in the FPGA fabric. The MPU subsystem, direct memory access (DMA) controller, and debug access port (DAP) can use the lightweight HPS-to-FPGA bridge to access the FPGA fabric or GPV. Master interfaces in the FPGA fabric can also use the lightweight HPS-to-FPGA bridge to access the GPV registers in all three bridges.

The bridge master exposed to the FPGA fabric has a fixed data width of 32 bits. The slave interface of the bridge in the HPS logic has a fixed data width of 32 bits.

Use the lightweight HPS-to-FPGA bridge as a secondary, lower-performance master interface to the FPGA fabric. With a fixed width and a smaller address space, the lightweight bridge is useful for low-bandwidth traffic, such as memory-mapped register accesses to FPGA peripherals. This approach diverts traffic from the high-performance HPS-to-FPGA bridge, and can improve both register access latency and overall system performance.

Table 9-14: Lightweight HPS-to-FPGA Bridge Properties

This table lists the properties of the lightweight HPS-to-FPGA bridge, including the master interface exposed to the FPGA fabric.

Bridge Property	L3 Slave Interface	FPGA Master Interface
Data width	32 bits	32 bits
Clock domain	14_mp_clk	h2f_lw_axi_clk
Byte address width	32 bits	21 bits
ID width	12 bits	12 bits
Read acceptance	16 transactions	16 transactions

Bridge Property	L3 Slave Interface	FPGA Master Interface
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

The lightweight HPS-to-FPGA bridge has three master interfaces. The master interface connected to the FPGA fabric provides a lightweight interface from the HPS to custom logic in the FPGA fabric. The two other master interfaces, connected to the HPS-to-FPGA and FPGA-to-HPS bridges, allow you to access the GPV registers for each bridge.

The lightweight HPS-to-FPGA bridge also has a set of registers GPV to control the behavior of its four interfaces (one slave and three masters).

The GPV allows you to set the bridge's issuing capabilities to support single or multiple transactions. The GPV also lets you set a write tidemark through the `wr_tidemark` register, to control how much data is buffered in the bridge before data is written to slaves in the FPGA fabric.

Note: It is critical to provide correct clock settings for the lightweight HPS-to-FPGA bridge, even if your design does not use this bridge. The `l4_mp_clk` clock is required for GPV access on the HPS-to-FPGA and FPGA-to-HPS bridges.

Lightweight HPS-to-FPGA Bridge Master Signals

All the lightweight HPS-to-FPGA bridge master signals have a fixed width.

The following tables list all the signals exposed by the lightweight HPS-to-FPGA master interface to the FPGA fabric.

Table 9-15: Lightweight HPS-to-FPGA Bridge Master Write Address Channel Signals

Signal	Width	Direction	Description
AWID	12 bits	Output	Write address ID
AWADDR	21 bits	Output	Write address
AWLEN	4 bits	Output	Burst length

Signal	Width	Direction	Description
AWSIZE	3 bits	Output	Burst size
AWBURST	2 bits	Output	Burst type
AWLOCK	2 bits	Output	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Output	Cache policy type
AWPROT	3 bits	Output	Protection type
AWVALID	1 bit	Output	Write address channel valid
AWREADY	1 bit	Input	Write address channel ready

Table 9-16: Lightweight HPS-to-FPGA Bridge Master Write Data Channel Signals

Signal	Width	Direction	Description
WID	12 bits	Output	Write ID
WDATA	32 bits	Output	Write data
WSTRB	4 bits	Output	Write data strobes
WLAST	1 bit	Output	Write last data identifier
WVALID	1 bit	Output	Write data channel valid
WREADY	1 bit	Input	Write data channel ready

Table 9-17: Lightweight HPS-to-FPGA Bridge Master Write Response Channel Signals

Signal	Width	Direction	Description
BID	12 bits	Input	Write response ID
BRESP	2 bits	Input	Write response
BVALID	1 bit	Input	Write response channel valid
BREADY	1 bit	Output	Write response channel ready

Table 9-18: Lightweight HPS-to-FPGA Bridge Master Read Address Channel Signals

FPGA Slaves Accessed Via Lightweight HPS2FPGA AXI Bridge (lwfpgaslaves) Address Map

This address space is allocated for FPGA-configured slaves driven by the lightweight HPS-to-FPGA bridge master. Address assignment within this space is user-defined. For more information about Lightweight HPS-to-FPGA bridges, refer to the *HPS-FPGA Bridges* chapter of the *Hard Processor System Technical Reference Manual*.

Table 9-20: lwfpgaslaves Address Range

Module Instance	Start Address	End Address
LWFPGASLAVES	0xFF200000	0xFF3FFFFFFF

Clocks and Resets

FPGA-to-HPS Bridge Clocks and Resets

The master interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The slave interface exposed to the FPGA fabric operates in the `f2h_axi_clk` clock domain provided by the user logic. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The FPGA-to-HPS bridge has one reset signal, `fpga2hps_bridge_rst_n`. The reset manager drives this signal to the FPGA-to-HPS bridge on a cold or warm reset.

Related Information

- [Clock Manager](#) on page 3-1
- [HPS Component Interfaces](#) on page 29-1
Information about the HPS-FPGA bridge clock interfaces

HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `h2f_axi_clk` clock domain. The `h2f_axi_clk` clock is provided by user logic. The slave interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The HPS-to-FPGA bridge has one reset signal, `hps2fpga_bridge_rst_n`. The reset manager drives this signal to the HPS-to-FPGA bridge on a cold or warm reset.

Related Information

Information about the HPS-FPGA bridge clock interfaces

Lightweight HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `h2f_lw_axi_clk` clock domain. The clock is provided by custom logic in the FPGA fabric. The slave interface of the bridge in the HPS logic operates in the `l4_mp_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The lightweight HPS-to-FPGA bridge has one reset signal, `lwhps2fpga_bridge_rst_n`. The reset manager drives this signal to the lightweight HPS-to-FPGA bridge on a cold or warm reset.

Related Information

Taking HPS-FPGA Bridges Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

[Modules Requiring Software Deassert](#) on page 4-9
Reset register names

GPV Clocks

The FPGA-to-HPS and HPS-to-FPGA bridges have GPV slave interfaces, mastered by the lightweight HPS-to-FPGA bridge. These interfaces operate in the `l4_mp_clk` clock domain. Even if you do not use the lightweight HPS-to-FPGA bridge in your FPGA design, you must ensure that a valid `l4_mp_clk` clock is

being generated, so that the GPV registers in the HPS-to-FPGA and FPGA-to-HPS bridges can be programmed. The GPV logic in all three bridges is in the `l4_mp_clk` domain.

Related Information

[The Global Programmers View](#) on page 9-4

Data Width Sizing

The HPS-to-FPGA and FPGA-to-HPS bridges allow 32-, 64-, and 128-bit interfaces to be exposed to the FPGA fabric. For 32-bit and 128-bit interfaces, the bridge performs data width conversion to the fixed 64-bit interface within the HPS. This conversion is called *upsizing* in the case of data being converted from a 64-bit interface to a 128-bit interface. It is called *downsizing* in the case of data being converted from a 64-bit interface to a 32-bit interface. If an exclusive access is split into multiple transactions, the transactions lose their exclusive access information.

During the upsizing or downsizing process, transactions can also be resized using a data merging technique. For example, in the case of a 32-bit to 64-bit upsizing, if the size of each beat entering the bridge's 32-bit interface is only two bytes, the bridge can merge up to four beats to form a single 64-bit beat. Similarly, in the case of a 128-bit to 64-bit downsizing, if the size of each beat entering the bridge's 128-bit interface is only four bytes, the bridge can merge two beats to form a single 64-bit beat.

The bridges do not perform transaction merging for accesses marked as noncacheable.

Note: You can set the `bypass_merge` bit in the GPV to prevent the bridge from merging data and responses. If the bridge merges multiple responses into a single response, that response is the one with the highest priority. The response types have the following priorities:

1. DECERR
2. SLVERR
3. OKAY

HPS-FPGA Bridges Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- FPGA-to-HPS Bridge Module
- HPS-to-FPGA Bridge Module
- Lightweight HPS-to-FPGA Bridge Module
- FPGA Slaves Accessed via Lightweight HPS-to-FPGA AXI Bridge

Related Information

- [FPGA2HPS AXI Bridge Module Address Map](#) on page 9-7

Send Feedback

The hard processor system (HPS) in the Intel SoC device includes a stand-alone, full-featured Arm Cortex-A9 MPCore, single- or dual-core 32-bit application processor. The Cortex-A9 microprocessor unit (MPU) subsystem is composed of a Cortex-A9 MPCore, a level 2 (L2) cache, an Accelerator Coherency Port (ACP) ID mapper, and debugging modules.

Features of the Cortex-A9 MPU Subsystem

The Intel Cortex-A9 MPU subsystem provides the following features:

- One or two Arm Cortex-A9 processors each with the following support modules:
 - Arm NEON single instruction, multiple data (SIMD) coprocessor
 - Memory Management Unit (MMU)
 - 32 KB instruction cache
 - 32 KB data cache
 - Private interval timer
 - Private watchdog timer
- Interrupt controller
- Global timer
- Snoop control unit (SCU)
- Accelerator Coherency Port (ACP)
- Arm L2 cache controller
- TrustZone system security extensions
- Symmetric multiprocessing (SMP) and asymmetric multiprocessing (AMP) modes
- Debugging modules

The Cortex-A9 MPU incorporates the following core and L2 cache versions:

Table 10-1: Cortex-A9 MPU Module Versions

Feature	Version
Cortex-A9 Core	r3p0
L2-310 Level 2 Cache Controller	r3p3

Cortex-A9 MPU Subsystem Block Diagram and System Integration

Cortex-A9 MPU Subsystem with System Interconnect

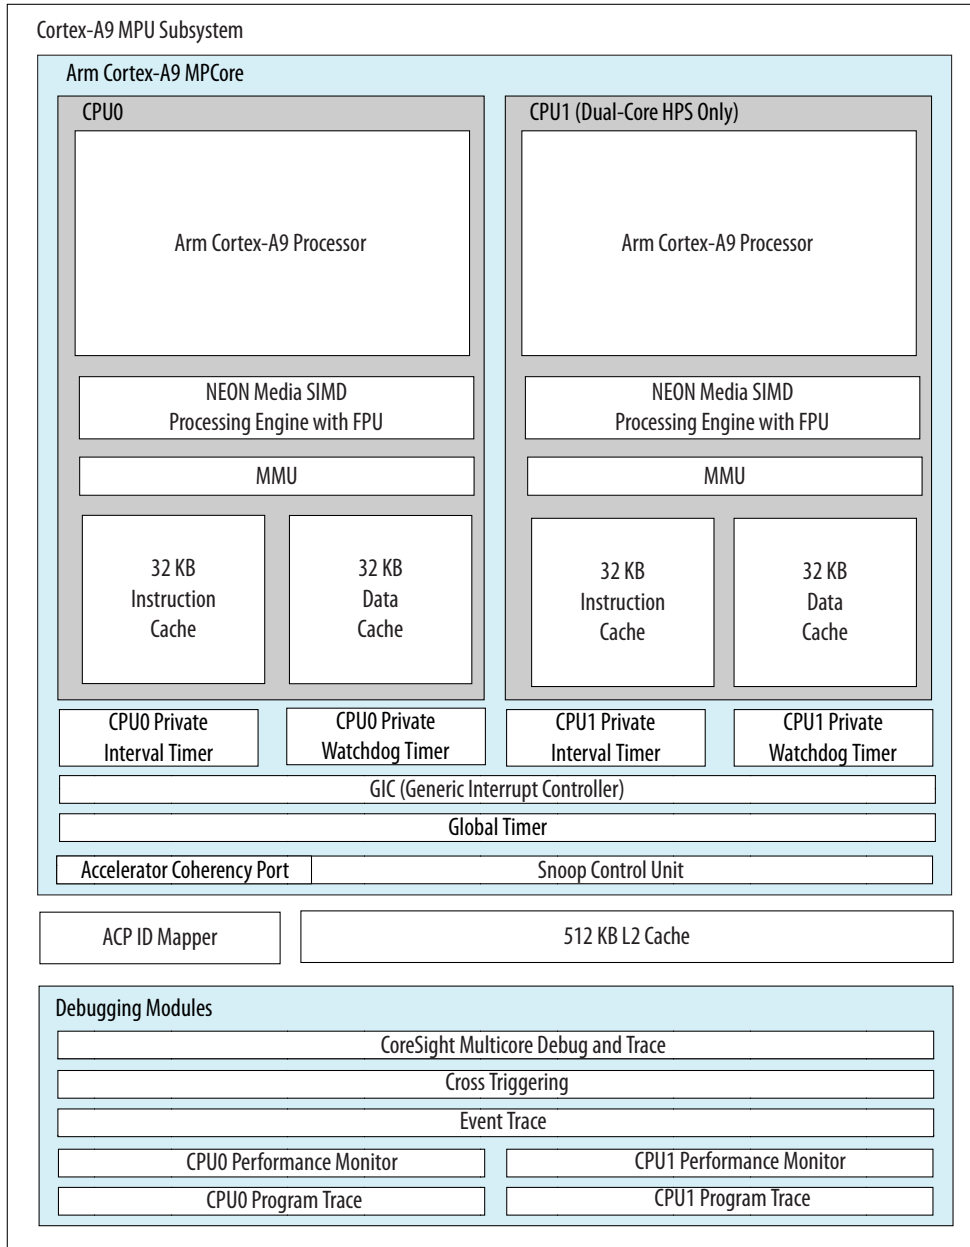

This block diagram shows a dual-core MPU subsystem in the context of the HPS, with the L2 cache. The L2 cache can access either the system interconnect or the SDRAM.

Figure 10-1: Cortex-A9 MPU Subsystem with Interconnect Block Diagram

Cortex-A9 MPU Subsystem Internals

Figure 10-2: Cortex-A9 MPU Subsystem Block Diagram

Cortex-A9 MPCore

The MPU subsystem includes a stand-alone, full-featured Arm Cortex-A9 MPCore single- or dual-core 32-bit application processor. The processor, like other HPS masters, can access IP in the FPGA fabric through the HPS-to-FPGA bridges.

Functional Description

The Arm Cortex-A9 MPCore contains the following sub-modules:

- One or two Cortex-A9 Revision r3p0 processors operating in SMP or AMP mode
- Snoop control unit (SCU)
- Private interval timer for each processor core
- Private watchdog timer for each processor core
- Global timer
- Interrupt controller

Each transaction originating from the Cortex-A9 MPU subsystem can be flagged as secure or non-secure.

Implementation Details

Table 10-2: Cortex-A9 MPCore Processor Configuration

This table shows the parameter settings for the Cortex-A9 MPCore.

Feature	Options
Cortex-A9 processors	1 or 2
Instruction cache size per Cortex-A9 processor	32 KB
Data cache size per Cortex-A9 processor	32 KB
TLB size per Cortex-A9 processor	128 entries
Media Processing Engine with NEON technology per Cortex-A9 processor ⁽²²⁾	Included
Preload Engine per Cortex-A9 processor	Included
Number of entries in the Preload Engine FIFO per Cortex-A9 processor	16
Jazelle DBX extension per Cortex-A9 processor	Full
Program Trace Macrocell (PTM) interface per Cortex-A9 processor	Included
Support for parity error detection ⁽²³⁾	Included
Master ports	Two
Accelerator Coherency Port	Included

Related Information

[Arm Infocenter](#)

For more information regarding the Cortex-A9 MPCore features and functions.

⁽²²⁾ Includes support for floating-point operations.

⁽²³⁾ For a description of the parity error scheme and parity error signals, refer to the Cortex-A9 Technical Reference Manual, available on the Arm website (infocenter.arm.com).

Cortex-A9 Processor

Each Cortex-A9 processor includes the following hardware blocks:

- Arm NEON single instruction, multiple data (SIMD) coprocessor with vector floating-point (VFP) v3 double-precision floating point unit for media and signal processing acceleration
 - Single- and double-precision IEEE-754 floating point math support
 - Integer and polynomial math support
- Level 1 (L1) cache with parity checking
 - 32 KB four-way set-associative instruction cache
 - 32 KB four-way set-associative data cache
- CoreSight Program Trace Macrocell (PTM) supporting instruction trace

Each Cortex-A9 processor supports the following features:

- Dual-issue superscalar pipeline with advanced branch prediction
- Out-of-order (OoO) dispatch and speculative instruction execution
- 2.5 million instructions per second (MIPS) per MHz, based on the Dhrystone 2.1 benchmark
- 128-entry translation lookaside buffer (TLB)
- TrustZone security extensions
- Configurable data endianness
- Jazelle* DBX Extensions for byte-code dynamic compiler support
- The Cortex-A9 processor architecture supports the following instruction sets:
 - The Armv7-A performance-optimized instruction set
 - The memory-optimized Thumb*-2 mixed instruction set
 - Improves energy efficiency
 - 31% smaller memory footprint
 - 38% faster than the original Thumb instruction set
 - The Thumb instruction set—supported for legacy applications
- Each processor core in the Intel HPS includes an MMU to support the memory management requirements of common modern operating systems.

The Cortex-A9 processors are designated CPU0 and CPU1.

Related Information

[Arm Infocenter](#)

Detailed documentation of Arm Cortex-A9 series processors is available on the Arm Infocenter website.

Reset

When a cold or warm reset is issued in the MPU, CPU0 is released from reset automatically. If CPU1 is present, then its reset signals are left asserted when a cold or warm reset is issued. After CPU0 comes out of reset, it can deassert CPU1's reset signals by clearing the CPU1 bit in the MPU Module Reset (mpumodr_{rst}) register in the Reset Manager.

Related Information

[Reset Manager](#) on page 4-1

Interactive Debugging Features

Each Cortex-A9 processor has built-in debugging capabilities, including six hardware breakpoints (two with Context ID comparison capability) and four watchpoints. The interactive debugging features can be controlled by external JTAG tools or by processor-based monitor code.

Related Information

[Arm Infocenter](#)

For more information about the interactive debugging system, refer to the *Debug* chapter of the Cortex-A9 Technical Reference Manual, available on the Arm Infocenter website.

L1 Caches

Cache memory that is closely coupled with an associated processor is called level 1, or L1 cache. Each Cortex-A9 processor has two independent 32 KB L1 caches—one for instructions and one for data—allowing simultaneous instruction fetches and data access. Each L1 cache is four-way set associative, with 32 bytes per line, and supports parity checking.

Note: A parity error cannot be recovered and is indicated by one of the parity error interrupt signals. On a parity error interrupt, you can reset the system or perform further actions depending on the indication of the interrupt signals.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

Preload Engine

The preload engine (PLE) is a hardware block that enables the L2 cache to preload selected regions of memory.

The PLE signals the L2 cache when a cache line is needed in the L2 cache, by making the processor data master port start fetching the data. The processor data master does not complete the fetch or return the data to the processor. However, the L2 cache can then proceed to load the cache line. The data is only loaded to the L2 cache, not to the L1 cache or processor registers.

The preload functionality is under software control. The following PLE control parameters must be programmed:

- Programmed parameters, including the following:
 - Base address
 - Length of stride
 - Number of blocks
- A valid bit
- TrustZone memory protection for the cache memory, with an NS (non-secure) state bit
- A translation table base (TTB) address
- An Address Space Identifier (ASID) value

Related Information**Arm Infocenter**

For more information about the PLE, refer to the *Preload Engine* chapter of the *Cortex-A9 Technical Reference Manual*, available on the Arm Infocenter website.

Floating Point Unit

Each Arm Cortex-A9 processor includes full support for IEEE-754 floating point operations.

The floating-point unit (FPU) can execute half-, single-, and double-precision variants of the following operations:

- Add
- Subtract
- Multiply
- Divide
- Multiply and accumulate (MAC)
- Square root

The FPU also converts between floating-point data formats and integers, including special operations to round towards zero required by high-level languages.

NEON Multimedia Processing Engine

The NEON multimedia processing engine (MPE) provides hardware acceleration for media and signal processing applications. Each CPU includes an Arm NEON MPE that supports SIMD processing.

Single Instruction, Multiple Data (SIMD) Processing

Features of the NEON MPE

The NEON processing engine accelerates multimedia and signal processing algorithms such as video encoding and decoding, 2-D and 3-D graphics, audio and speech processing, image processing, telephony, and sound synthesis.

The Cortex-A9 NEON MPE performs the following types of operations:

- SIMD and scalar single-precision floating-point computations
- Scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- 8-, 16-, 32-, and 64-bit signed and unsigned integer SIMD computation
- 8-bit or 16-bit polynomial computation for single-bit coefficients

The following operations are available:

- Addition and subtraction
- Multiplication with optional accumulation (MAC)
- Maximum- or minimum-value driven lane selection operations
- Inverse square root approximation
- Comprehensive data-structure load instructions, including register-bank-resident table lookup

Related Information

[Arm Infocenter](#)

For more information about the Cortex-A9 NEON MPE, refer to the Cortex-A9 NEON Media Processing Engine Technical Reference Manual, which you can download from the Arm Infocenter website.

Memory Management Unit

The MMU is used in conjunction with the L1 and L2 caches to translate virtual addresses used by software to physical addresses used by hardware. Each processor has a private MMU.

TLBs Supported By the MMU

TLB Type	Memory Type	Number of Entries	Associativity
Micro TLB	Instruction	32	Fully associative
Micro TLB	Data	32	Fully associative
Main TLB	Instruction and Data	128	Two-way associative

TLB Features

The main TLB has the following features:

- Lockable entries using the lock-by-entry model
- Supports hardware page table walks to perform look-ups in the L1 data cache

The MPU address map is divided into the following regions:

- The boot region
- The SDRAM region
- The FPGA slaves region
- The HPS peripherals region

Note: The `SMP` bit in the `ACTLR` register must be set before enabling the MMU.

Related Information

[Arm Infocenter](#)

For more information about the MMU, refer to the *Memory Management Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the Arm Infocenter website.

The Boot Region

The boot region is 1 MB in size, based at address 0. After power-on, or after reset of the system interconnect, the boot region is occupied by the boot ROM, allowing the Cortex-A9 MPCore to boot. Although the boot region size is 1 MB, accesses beyond 64 KB are illegal because the boot ROM is only 64 KB.

The 1 MB boot region can be subsequently remapped to the bottom 1 MB of SDRAM region by adjusting the L2 cache address filter.

Note: Alternatively, the boot region can be mapped to the 64 KB on-chip RAM.

Related Information

- [Address Remapping](#) on page 8-11
For more information about address remapping
- [System Interconnect](#) on page 8-1

Boot ROM Mapping

Addresses Are Not To Scale

The SDRAM Region

The SDRAM region starts at address 0x100000 (1 MB). The top of the region is determined by the L2 cache filter.

The L2 cache contains a filtering mechanism that routes accesses to the SDRAM and system interconnect. The filter defines a filter range with start and end addresses. Any access within this filter range is routed to the SDRAM subsystem. Accesses outside of this filter range are routed to the system interconnect.

The start and end addresses are specified in the following register fields:

- `reg12_addr_filtering_start.address_filtering_start`
- `reg12_address_filtering_end.address_filtering_end`

To remap the lower 1MB of SDRAM into the boot region, set the filter start address to 0x0 to ensure accesses between 0x0 and 0xFFFFF are routed to the SDRAM. Independently, you can set the filter end address in 1 MB increments above 0xC0000000 to extend the upper bounds of the SDRAM region. However, you achieve this extended range at the expense of the FPGA peripheral address span. Depending on the address filter settings in the L2 cache, the top of the SDRAM region can range from 0xBFFFFFFF to 0xFBFFFFFFF.

Related Information[L2 Cache](#) on page 10-62

The FPGA Slaves Region

The Cortex-A9 MPU subsystem supports the variable-sized FPGA slaves region to communicate with FPGA-based peripherals. This region can start as low as 0xC0000000, depending on the L2 cache filter settings. The top of the FPGA slaves region is located at 0xFBFFFFFF. As a result, the size of the FPGA slaves region can range from 0 to 0x3C000000 bytes.

The HPS Peripherals Region

The HPS peripherals region is the top 64 MB in the address space, starting at 0xFC000000 and extending to 0xFFFFFFFF. The HPS peripherals region is always allocated to the HPS dedicated peripherals for the Cortex-A9 MPU subsystem.

Performance Monitoring Unit

Each Cortex-A9 processor has a Performance Monitoring Unit (PMU). The PMU supports 58 events to gather statistics on the operation of the processor and memory system. Six counters in the PMU accumulate the events in real time. The PMU counters are accessible either from the processor itself, using the Coprocessor 14 (CP14) interface, or from an external debugger. The events are also supplied to the PTM and can be used for trigger or trace.

Related Information[Arm Infocenter](#)

For more information about the PMU, refer to the *Performance Monitoring Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the Arm Infocenter website.

Arm Cortex-A9 MPCore Timers

There is one interval timer and one watchdog timer for each processor.

Functional Description

Each timer is private, meaning that only its associated processor can access it. If the watchdog timer is not needed, it can be configured as a second interval timer.

Each private interval and watchdog timer has the following features:

- A 32-bit counter that optionally generates an interrupt when it reaches zero
- Configurable starting values for the counter
- An eight-bit prescaler value to qualify the clock period

Implementation Details

The timers are configurable to either single-shot or auto-reload mode. The timer blocks are clocked by `mpu_periph_clk` running at $\frac{1}{4}$ the rate of the `mpu_clk`.

Related Information

[Arm Infocenter](#)

For more information about private timers, refer to “About the private timer and watchdog blocks” in the *Global timer, Private timers, and Watchdog registers* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the Arm Infocenter website.

Generic Interrupt Controller

Functional Description

The PL390 Generic Interrupt Controller (GIC) supports up to 180 interrupt sources, including dedicated peripherals and IP implemented in the FPGA fabric. In a dual-core system, the GIC is shared by both Cortex-A9 processors. Each processor also has 16 banked software-generated interrupts and 16 banked private peripheral interrupts, which occupy GIC interrupt numbers 0 to 31.

Implementation Details

The configuration and control for the GIC is memory-mapped and accessed through the SCU. The GIC are clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Related Information

Global Timer

The MPU features a global 64-bit, auto-incrementing timer, which is primarily used by the operating system.

Functional Description

The global timer is accessible by the processors using memory-mapped access through the SCU. The global timer has the following features:

- 64-bit incrementing counter with an auto-incrementing feature. It continues incrementing after sending interrupts.
- Memory-mapped in the private memory region.
- Accessed at reset in Secure State only. It can only be set once, but secure code can read it at any time.
- Accessible to both Cortex-A9 processors in the MPCore.
- Clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Implementation Details

Each Cortex-A9 processor has a private 64-bit comparator that generates a private interrupt when the counter reaches the specified value. Each Cortex-A9 processor uses the banked ID, ID27, for this interrupt. ID27 is sent to the GIC as a Private Peripheral Interrupt (PPI).

The global timer is clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

For more information about the global timer, refer to “About the Global Timer” in the *Global timer, Private timers, and Watchdog registers* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the Arm Infocenter website.

Snoop Control Unit

The SCU manages data traffic for the Cortex-A9 processors and the memory system, including the L2 cache. In a multi-master system, the processors and other masters can operate on shared data. The SCU ensures that each processor operates on the most up-to-date copy of data, maintaining cache coherency.

Functional Description

The SCU is used to connect the Cortex-A9 processors and the ACP to the L2 cache controller. The SCU performs the following functions:

- When the processors are set to SMP mode, the SCU maintains data cache coherency between the processors.

Note: The SCU does not maintain coherency of the instruction caches.

- Initiates L2 cache memory accesses
- Arbitrates between processors requesting L2 access
- Manages ACP access with cache coherency capabilities.

Coherent Memory, Snoop Control Unit, and Accelerator Coherency Port

Figure 10-3: Data Flow Between L1 Caches and SCU

This diagram illustrates the flow of data among the L1 data caches and the SCU.

Related Information

[Accelerator Coherency Port](#) on page 10-27

Implementation Details

When the processor writes to any coherent memory location, the SCU ensures that the relevant data is coherent (updated, tagged or invalidated). Similarly, the SCU monitors read operations from a coherent memory location. If the required data is already stored within the other processor's L1 cache, the data is returned directly to the requesting processor. If the data is not in L1 cache, the SCU issues a read to the L2 cache. If the data is not in the L2 cache memory, the read is finally forwarded to main memory. The primary goal is to maximize overall memory performance and minimize power consumption.

The SCU maintains bidirectional coherency between the L1 data caches belonging to the processors. When one processor performs a cacheable write, if the same location is cached in the other L1 cache, the SCU updates it.

Non-coherent data passes through as a standard read or write operation.

The SCU also arbitrates between the Cortex-A9 processors if both attempt simultaneous access to the L2 cache, and manages accesses from the ACP.

In rare circumstances, when the aggregate memory throughput requested by two cores exceeds the memory subsystem capacity and the Acceleration Coherency Port (ACP) is not being used, you may observe that the SCU master arbitration fairness is reduced. This reduction occurs because unused ACP arbitration shares are reassigned to CPU0, resulting in CPU0 gaining twice the memory bandwidth of CPU1. If your application requires a balanced throughput between CPU0 and CPU1, you must design the code that runs on CPU0 so that it prevents CPU0 from using more than 50% of the available memory bandwidth.

Accelerator Coherency Port

The ACP allows master peripherals—including FPGA-based peripherals—to maintain data coherency with the Cortex-A9 MPCore processors and the SCU. Dedicated master peripherals in the HPS, and those built in FPGA logic, access the coherent memory through the ACP ID mapper and the ACP.

The ACP port allows one-way coherency. One-way coherency allows an external ACP master to see the coherent memory of the Cortex-A9 processors but does not allow the Cortex-A9 processors to see memory changes outside of the cache.

A master on the ACP port can read coherent memory directly from the L1 and L2 caches, but cannot write directly to the L1 cache. The possible ACP master read and write scenarios are as follows:

- ACP master read with coherent data in the L1 cache: The ACP gets data directly from the L1 cache and the read is interleaved with a processor access to the L1 cache.
- ACP master read with coherent data in L2 cache: The ACP request is queued in the SCU and the transaction is sent to the L2 cache.
- ACP master read with coherent data not in L1 or L2 cache: Depending on the previous state of the data, the L1 or L2 cache may request the data from the L3 system interconnect. The ACP is stalled until data is available, however ACP support of multiple outstanding transactions minimizes bottlenecks.
- ACP master write with coherent data in the L1 cache: The L1 cache data is marked as invalid in the Cortex-A9 MPU and the line is evicted from the L1 cache and sent to L2 memory. The ACP write data is scheduled in the SCU and is eventually written to the L2 cache. Later, when the Cortex-A9 processor accesses the same memory location, a cache miss in the L1 occurs.
- ACP master write, with coherent data in the L2 cache: The ACP write is scheduled in the SCU and then is written into the L2 cache.
- ACP master write, with coherent data not in L1 or L2 cache: ACP write is scheduled.

Note: The entire 4 GB address space can be accessed coherently through the ACP through a 1 GB coherent window implemented through the ACP ID mapper.

Note: Refer to the Cyclone V SoC device errata for details on Arm errata that directly affect the ACP.

AxUSER and AxCACHE Attributes

ARUSER[0] and AWUSER[0] Bits

The table below shows how the `AXUSER[0]` bit determines whether a request is shared or non-shared. `ARUSER[0]` applies to read transactions, and `AWUSER[0]` applies to write transactions.

Table 10-4: ARUSER[0] or AWUSER[0] Sideband Signal Information

<code>ARUSER[0]</code> or <code>AWUSER[0]</code>	Sideband Signal Information
1	Shared request
0	Non-shared request

Other `AXUSER` bits from the ACP are not interpreted by the SCU but are forwarded to the L2 cache.

Note: Except for the FPGA-to-HPS masters, the ACP ID mapper provides the `AXUSER` signals for all other masters.

ARCACHE[4:0] and AWCACHE[4:0] Bits

The Cortex-A9 MPU only interprets `ARCACHE[1]` and `AWCACHE[1]` from ACP requests. All other attributes are forwarded to the L2 cache. `AXCACHE[1]` is used in combination with `AXUSER[0]` to detect a coherent access. If `AXCACHE[1]=0x1`, (normal memory) and `AXUSER[0]=0x1`, then the access is considered coherent. All ACP requests with `AXCACHE[1]=0x0` or `AXUSER[0]=0x0` are seen as non-coherent requests.

Table 10-5: ARUSER[0] or AWUSER[0] Sideband Signal Information

ARCACHE[1] or AWCACHE[1]	ARUSER[0] or AWUSER[0]	Access Type
1	1	Coherent request
0	0	Non-coherent request

Related Information

[Control of the AXI User Sideband Signals](#) on page 10-36

Cache Coherency for ACP Shared Requests

When a shared access is received on the ACP, caches are checked for coherency of the requested address. A shared access occurs when two masters access the same memory space.

This coherency check is performed by the SCU. If a cache hit occurs during a write access, the affected cache lines are cleaned and invalidated. This event may cause an eviction from the L1 cache to be sent to L2 memory if the L1 cache line is dirty. Once the invalidation and possible eviction is completed, the ACP write request is written to L2 memory. If an eviction was executed from L1 cache, then two consecutive writes to L2 memory occur over the AXI bus: the write from the eviction and the write from the ACP.

For a cache hit during a read access, the L1 cache line is provided by the CPU and is returned to the ACP.

For a cache miss during a write access, the invalidation is considered as complete and the ACP request is sent to L2 memory.

For a cache miss during a read access, the request is forwarded to L2 memory, which returns the data directly to the ACP.

Note: Shared write requests are always transferred to the L2 memory once the cache line is potentially clean and invalidated in the L1 cache memory. Reads are observed on the L2 only if they miss in the L1 cache.

AXI Master Configuration for ACP Access

To use the ACP for coherent accesses, the following configurations apply:

ACP master configurations must be as follows:

- The master module must target the ACP in physical memory (address 0x80000000 to 0xC0000000)
- For coherent ACP read accesses, the AXI bits must be programmed as follows to avoid compromising coherency:
 - `AXCACHE[3:0]` attributes must match the properties defined in the Cortex-A9 MPCore MMU page tables for the relevant memory region.
 - Shareable attribute `AXUSER[0]` must be set to 0x1

The Cortex-A9 MPCore configuration for ACP use should be as follows:

- The Snoop Control Unit must be enabled (by setting the SCU enable bit in the SCU Control Register at 0xFFFE0000).
- Coherent memory must be marked cacheable and shareable.
- The `SMP` bit of the `ACTLR` register must be set in the Cortex-A9 processor that shares data over the ACP.

Note: It is recommended that the `shared attribute override enable bit [22]` in the `Auxiliary Control` register is set. Enabling this bit disables optimizations in the L2 cache controller that can

change the point of coherency and cause errors. If this bit is clear, non-cacheable accesses from the MPU cores or ACP port may be transformed into cacheable non-allocated accesses and the point of coherency moves from the SDRAM to the L2 cache.

Note: To achieve maximum performance on the ACP, avoid switching from shared to non-shared requests and vice-versa. When a shared request is latched in the ACP and there are non-shared requests still pending, the non-shared requests must be completed before the shared request can proceed.

The following sections detail the attribute configurations necessary to support coherency.

Configuring AxCACHE[3:0] Sideband Signals for Coherent Accesses

The following list highlights how to correctly derive and apply the correct AxCACHE settings for coherent accesses.

- The correct AxCACHE[3:0] setting is dependent on the MMU page table settings. However, for coherent accesses, AxCACHE[1] must be set to 0x1.
- If an HPS peripheral uses the ACP for coherent master accesses, then the AxCACHE properties must be configured in the corresponding System Manager register for that peripheral and the ACP ID mapper must be configured for the appropriate AxUSER properties.
- For FPGA masters, AxCACHE[3:0] is applied in the FPGA fabric and can be set for each access.

Configuring AxUSER[4:0] Sideband Signals

The following list highlights how to correctly derive and apply the correct AxUSER settings for coherent accesses.

- AxUSER[0] (shared attribute) must be set to 0x1 for coherent accesses.
- Because the ACP has no inner cache policy, AxUSER[3:1] is not interpreted by the SCU. AxUSER[3:1] attributes pass to the L2 cache controller and are used when the cache is operating in exclusive mode.
- For HPS masters, AxUSER[4:0] is applied on the ACP ID Mapper.
- For FPGA masters, AxUSER[4:0] is applied in the FPGA fabric and can be set for each access.

Burst Sizes and Byte Strobes

The ACP improves system performance for hardware accelerators in the FPGA fabric. However, in order to achieve high levels of performance, you must use the one of the optimized burst types. Other burst configurations have significantly lower performance.

Recommended Burst Types

Table 10-6: Recommended Burst Types for Optimized Bursts

Burst Type	Beats	Width (Bits)	Address Type	Byte Strobes
Wrapping	4	64	64-bit aligned	Asserted
Incrementing	4	64	32-bit aligned	Asserted

Note: If the slave port of the FPGA-to-HPS bridge is not 64 bits wide, you must supply bursts to the FPGA-to-HPS bridge that are upsized or downsized to the burst types above. For example, if the slave data width of the FPGA-to-HPS bridge is 32 bits, then bursts of eight beats by 32 bits are required to access the ACP efficiently.

Note: If the address and burst size of the transaction to the ACP matches either of the conditions shown in the table "Recommended Burst Types for Optimized Bursts", the logic in the MPU assumes the transaction has all its byte strobes set. If the byte strobes are not all set, then the write does not actually overwrite all the bytes in the word. Instead, the cache assumes the whole cache line is valid. If this line is dirty (and therefore gets written out to SDRAM), data corruption might occur.

In addition to optimizing performance, using a 64-bit access width will allow you to use ECC. ECC is only supported for 64-bit accesses that are 64-bit aligned..

Related Information

[Single Event Upset Protection](#) on page 10-65

Exclusive and Locked Accesses

The ACP does not support exclusive accesses to coherent memory. Exclusive accesses to non-coherent memory can be generated, however, it is important that the exclusive access transaction is not affected by the upsizing and downsizing logic of the FPGA-to-HPS bridge or the system interconnect. If the exclusive access is broken into multiple transactions due to the sizing logic, the exclusive access bit is cleared by the bridge or interconnect and the exclusive access fails.

Note: Intel recommends that exclusive accesses bypass the ACP altogether, either through the 32-bit slave port of the SDRAM controller connected directly to the system interconnect or through the FPGA-to-SDRAM interface.

The ACP ID mapper does not support locked accesses. To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM controller.

Related Information

[SDRAM Controller Subsystem](#) on page 12-1

For more information about the exclusive access support of the SDRAM controller subsystem, refer to the *SDRAM Controller Subsystem* chapter.

Avoiding ACP Dependency Lockup

Certain coherent access scenarios can create deadlock through the ACP and the CPU. However, you can avoid this type of deadlock with a simple access strategy.

In the following example, the CPU creates deadlock by initiating an access to the HPS through the FPGA fabric:

1. The CPU initiates a device memory access to the FPGA fabric. The CPU pipeline must stall until this type of access is complete.
2. Before the FPGA fabric state machine can respond to the device memory access, it must access the HPS coherently. It initiates a coherent access, which requires the ACP.
3. The ACP must perform a cache maintenance operation before it can complete the access. However, the CPU's pipeline stall prevents it from performing the cache maintenance operation. The system deadlocks.

You can implement the desired access without deadlock, by breaking it into smaller pieces. For example, you can initiate the operation with one access, then determine the operation status with a second access.

ACP ID Mapper

The ACP ID mapper is situated between the level 3 (L3) interconnect and the MPU subsystem ACP slave. It is responsible for mapping 12-bit Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) IDs (input IDs) from the system interconnect to 3-bit AXI IDs (output IDs) supported by the ACP slave port.

The ACP ID mapper also implements a 1 GB coherent window into the 4 GB Arm Cortex-A9 MPCore address space.

Functional Description

The ACP slave supports up to six masters. However, custom peripherals implemented in the FPGA fabric can have a larger number of masters that need to access the ACP slave. The ACP ID mapper allows these masters to access the ACP.

The ACP ID mapper resides between the interconnect and the ACP slave of the MPU subsystem. It has the following characteristics:

- Support for up to six concurrent ID mappings
- 1 GB coherent window into 4 GB Arm Cortex-A9 MPCore address space
- Remaps the 5-bit user sideband signals used by the Snoop Control Unit (SCU) and L2 cache

Related Information

[Arm Infocenter](#)

For more information about AXI user sideband signals, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available from the Arm Infocenter website.

Implementation Details

The ACP is accessed by masters that require access to coherent memory. The ACP slave port can be accessed by the master peripherals of the L3 interconnect, as well as by masters implemented in the FPGA fabric (via the FPGA-to-HPS bridge).

The ACP ID mapper supports the following ID mapping modes:

- Dynamic mapping
- Fixed mapping

Software can select the ID mapping on a per-ID basis. For input IDs that are configured for fixed mapping, there is a one-to-one mapping from input IDs to output IDs. When an input ID is configured for dynamic mapping, it is automatically mapped to an available output ID. The dynamic mode is more flexible because the hardware handles the mapping. The hardware mapping allows you to use one output ID for more than one input ID. Output IDs are assigned to input IDs on a first-come, first-served basis.

Note: If the number of differently configured masters exceeds the number available in fixed mode, you must use dynamic mode and ensure that the same `AXUSER` settings are used among all dynamic masters.

Out of the total of eight output IDs, only six are available to masters of the system interconnect. The first two output IDs (0 and 1) are dedicated to the Cortex-A9 processor cores in the MPU subsystem, leaving the last six output IDs (2-7) available to the ACP ID mapper. Output IDs 2-6 support fixed and dynamic modes of operation while output ID 7 supports dynamic only.

The operating modes are programmable through accesses to the control and status registers in the ACP ID mapper. At reset time, the ACP ID mapper defaults to dynamic ID mapping for all output IDs except ID 2, which resets to a fixed mapping for the Debug Access Port (DAP) input ID.

Related Information

[Cortex-A9 MPU Subsystem with System Interconnect](#) on page 10-2

ID Intended Usage

Table 10-7 summarizes the expected usage of the 3-bit output IDs, and their settings at reset.

Table 10-7: ID Intended Usage

Output ID	Reset State	Intended Use
7	Dynamic	Dynamic mapping only
6	Dynamic	Fixed or dynamic, programmed by software.
5		
4		
3	Statistically assigned to DAP (ID 0x005)	Assigned to the input ID of the DAP at reset. After reset, can be either fixed or dynamic, programmed by software.
2		

Output ID	Reset State	Intended Use
1	—	Not used by the ACP ID Mapper because these IDs are assigned to CPU0 and CPU1. ID=0 is for CPU0 and ID=1 is for CPU1.
0		

AXI User Sideband Override

For masters that cannot drive the AXI user sideband signal of incoming transactions, the ACP ID mapper can control overriding this signal. The ACP ID mapper can also control which 1 GB coherent window into memory is accessed by masters of the system interconnect. Each fixed mapping can be assigned a different user sideband signal and memory window to allow specific settings for different masters. All dynamic mappings share a common user sideband signal and memory window setting.

Transaction Capabilities

At any one time, the ACP ID mapper can accept and issue up to 15 transactions per ID mapping. Read and write ID mappings are managed in separate lists, allowing more unique input IDs to be remapped at any given time. If a master issues a series of reads and writes with the same input ID, there are no ordering restrictions.

Because there are only six output IDs available, there can be no more than six read and six write transactions with unique IDs in progress at any one time. The write acceptance of the ACP slave is five transactions, and the read acceptance is 13 transactions. Only four coherent read transactions per ID mapping can be outstanding at one time.

Dynamic Mapping Mode

In dynamic mode, every unique input ID that is received from the L3 master port is assigned to an unused output ID. The new output ID is applied to the transaction as it is issued to the ACP slave of the SCU. Any transaction that arrives to the ACP ID mapper with an input ID that matches an already-in-progress transaction is mapped to the same output ID. Once all transactions on an ID mapping have completed, that output ID is released and can be used again for other input IDs.

Fixed Mapping Mode

In fixed mode, output IDs 2 through 6 can be assigned by software to specific 12-bit input IDs. This ability makes it possible to use the lock-by-master feature of the L2 cache controller, because the input transaction ID from the master is always assigned to a specific output ID. ID 7 is not available for fixed mapping because it is reserved for dynamic mode only to avoid system deadlocks.

The ACP ID mapper can control the behavior of read and write virtual fixed ID mappings through the `vid*rd` and `vid*wr` registers. By programming the `force` bit to 0x1 in the `vid*rd` and `vid*wr` registers, the 12-bit `mid` field is forced to a specific 3-bit virtual ID. The `mid` field can be different between the read and write AXI Master Mapping registers. When these registers are programmed, hardware examines the request, and only applies the change when safe to do so, which is when there are no outstanding transactions with the output ID. When the change is applied, the status register is updated. Software should check that the change has actually taken place by polling the corresponding status register.

HPS Peripheral Master Input IDs

The following table identifies the ID that must be programmed in the `mid` field of the `vid*rd` and `vid*wr` registers, if an HPS master requires a fixed ACP mapping. The first column of the table gives the generic ID encoding, where the "x"s represent bits that change based on if the `vid*rd` or `vid*wr` register is being configured.

Table 10-8: HPS Peripheral Master Input IDs

The input IDs issued by the interconnect for each HPS peripheral master that can access the ACP ID mapper

Interconnect Master	ID ⁽²⁴⁾	<code>vid*rd.mid</code>	<code>vid*wr.mid</code>
DMA	0000 0xxx x001	"x" should indicate the total number of DMA channels. When the DMA performs an ACP read, the DMA controller signals the x values to be the same number as the number of DMA channels that the DMA controller provides. For example, if the DMA controller provides eight DMA channels, the x values must be set to 4'b1000.	"x" should indicate the number of the channel performing the write. When a DMA channel performs an ACP write, the DMA controller signals the x values to be the same number as the DMA channel. For example, when DMA channel 5 performs a DMA store operation, the DMA Controller sets the x values to 4'b0101.
EMAC0	1000 0000 x001	When x=0, this indicates the EMAC0 Rx channel is accessing memory and when x=1, this indicates the EMAC0 Tx channel is accessing memory. Each channel, Rx and Tx, requires read access to memory. This requirement exists because each channel DMA controller reads descriptors from memory when the packet is moved to or from memory. If you use static ACP ID mapping, you must allocate two static mappings for EMAC0: one for x=0 and one for x=1.	When x=0, this indicates the EMAC0 Rx channel is accessing memory and when x=1, this indicates the EMAC0 Tx channel is accessing memory. Each channel, Rx and Tx, requires write access to memory. This requirement exists because each channel DMA controller writes descriptors to memory when the packet is moved to or from memory. If you use static ACP ID mapping, then you need to allocate two static mappings for EMAC0: one for x=0 and one for x=1.

⁽²⁴⁾ Values are in binary. The letter x denotes variable ID bits that each master passes with each transaction.

Interconnect Master	ID ⁽²⁴⁾	vid*rd.mid	vid*wr.mid
EMAC1	1000 0000 x010	When x=0, this indicates the EMAC1 Rx channel is accessing memory and when x=1, this indicates the EMAC1 Tx channel is accessing memory. Each channel, Rx and Tx, requires read access to memory. This requirement exists because each channel DMA controller reads descriptors from memory when the packet is moved to or from memory. If you use static ACP ID mapping, then you must allocate two static mappings for EMAC1: one for x=0 and one for x=1. [ACP ID Mapper Address Map and Register Definitions](#) on page 10-37

This section lists the ACP ID Mapper register address map and describes the registers.

Control of the AXI User Sideband Signals

The ACP ID mapper module allows control of the AXI user sideband signal values. Not all masters drive these signals, so the ACP ID mapper makes it possible to drive the 5-bit user sideband signal with either a

⁽²⁴⁾ Values are in binary. The letter *x* denotes variable ID bits that each master passes with each transaction.

default value (in dynamic mode) or specific values (in fixed mode). The sideband signals are controlled through the ACP port. Sideband signals `AWUSER[4:1]` convey the inner cache attributes and `AWUSER[0]` determines whether the transaction is a shared cache access.

There are registers available to configure the default values of the user sideband signals for all transactions, and fixed values of these signals for particular transactions in fixed mapping mode. In dynamic mode, the user sideband signals of incoming transactions are mapped with the default values stored in the register. In fixed mapping mode, the input ID of the transaction is mapped to the 3-bit output ID and the user sideband signals of the transaction are mapped with the values stored in the register that corresponds to the output ID. One important exception, however, is that the ACP ID mapper always allows user sideband signals from the FPGA-to-HPS bridge to pass through to the ACP regardless of the user sideband value associated with the ID.

Note: For coherent, cacheable reads or writes, the `user` field of the `vid*rd` and `vid*wr` registers must be set to a binary value of `5'b11111` (coherent write back, write allocate inner cache attribute). This configuration ensures that the inner cache policy matches the policy used for cacheable data written by the processor.

Memory Region Remap

The ACP ID mapper has 1 GB of address space, which is by default a view into the bottom 1 GB of SDRAM. The mapper also allows transactions to be routed to different 1 GB-sized memory regions, called pages, in both dynamic and fixed modes. The two most significant bits of incoming 32-bit AXI address signals are replaced with the 2-bit user-configured address page decode information. The page decoder uses the values shown in [Table 10-9](#).

Table 10-9: Page Decoder Values

Page	Address Range
0	0x00000000–0x3FFFFFFF
1	0x40000000–0x7FFFFFFF
2	0x80000000–0xBFFFFFFF
3	0xC0000000–0xFFFFFFFF

With this page decode information, a master can read or write to any 1 GB region of the 4 GB memory space while maintaining cache coherency with the MPU subsystem.

Using this feature, a debugger can have a coherent view into main memory, without having to stop the processor. For example, at reset the DAP input ID (0x001) is mapped to output ID 2, so the debugger can vary the 1 GB window that the DAP accesses without affecting any other traffic flow to the ACP.

L2 Cache

The MPU subsystem includes a secondary 512 KB L2 shared, unified cache memory.

Functional Description

The L2 cache is much larger than the L1 cache. The L2 cache has significantly lower latency than external memory. The L2 cache is up to eight-way associative, configurable down to one-way (direct mapped). Like the L1 cache, the L2 cache can be locked by cache line, locked by way, or locked by master (CPU and ACP masters).

The L2 cache implements error correction codes (ECCs) and ECC error reporting. The cache can report a number of events to the processor and operating system.

Related Information

[Cortex-A9 MPU Subsystem Register Implementation](#) on page 10-71

For more information regarding the L2 Cache Controller Address Map, refer to the *Cortex-A9 MPU Subsystem Register Implementation* section.

Cache Controller Configuration

The L2 cache consists of the Arm L2C-310 L2 cache controller configured as follows:

- 512 KB total memory
- Eight-way associativity
- Physically addressed, physically tagged
- Line length of 32 bytes
- Critical first word linefills
- Support for all AXI cache modes
 - Write-through
 - Write-back
 - Read allocate
 - Write allocate
 - Read and write allocate
- Single event upset (SEU) protection
 - Parity on Tag RAM
 - ECC on L2 Data RAM
- Two slave ports mastered by the SCU

- Two master ports connected to the following slave ports:
 - SDRAM controller, 64-bit slave port width
 - L3 interconnect, 64-bit slave port width
- Cache lockdown capabilities as follows:
 - Line lockdown
 - Lockdown by way
 - Lockdown by master (both processors and ACP masters)
- TrustZone support
- Cache event monitoring

Related Information

For more information about AXI user sideband signals, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, which you can download from the Arm Infocenter website.

Implementation Details

The following table shows the parameter settings for the cache controller.

Table 10-10: Cache Controller Configuration

Feature	Meaning
Cache way size	64 KB
Number of cache ways	8 ways
Tag RAM write latency	1
Tag RAM read latency	1
Tag RAM setup latency	1
Data RAM write latency	1
Data RAM read latency	2
Data RAM setup latency	1
Parity logic	Parity logic enabled
Lockdown by master	Lockdown by master enabled
Lockdown by line	Lockdown by line enabled

Feature	Meaning
AXI ID width on slave ports	6 AXI ID bits on slave ports
Address filtering	Address filtering logic enabled
Speculative read	Logic for supporting speculative read enabled
Presence of ARUSERMx and AWUSERMx sideband signals	Sideband signals enabled

Related Information

For further information about cache controller configurable options, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available on the Arm Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 10-11: L2 Cache Events

Event	Description
CO	Eviction (cast out) of a line from the L2 cache.
DRHIT	Data read hit in the L2 cache.
DRREQ	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
DWHIT	Data write hit in the L2 cache.
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.

Event	Description
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
SRCONFS1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

[Arm Infocenter](#)

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the Arm Infocenter website.

Single Event Upset Protection

The L2 cache has the option of using ECCs to protect against Single Event Upset (SEU) errors in the cache RAM.

The L2 cache has two types of protection:

- The L2 cache tag RAMs are protected by parity.
- The L2 cache data RAMs are protected using single error correction, double error detection (SECDED) ECC Hamming code.

Enabling ECCs does not affect the performance of the L2 cache. The ECC bits are calculated only for writes to the data RAM that are 64 bits wide (8 bytes, or one-quarter of the cache line length). The ECC logic does not perform a read-modify-write when calculating the ECC bits.

The ECC protection bits are not valid in the following cases:

- Data is written that is not 64-bit aligned in memory
- Data is written that is less than 64 bits in width

In these cases the Byte Write Error interrupt is asserted. Cache data is still written when such an error occurs. However, the ECC error detection and correction continues to function. Therefore, the cache data is likely to be incorrect on subsequent reads.

To use ECCs, the software and system must meet the following requirements:

- L1 and L2 cache must be configured as write-back and write-allocate for any cacheable memory region
- Level 3 interconnect masters using the ACP must only perform the following types of data writes:
 - 64-bit aligned in memory
 - 64-bit wide accesses

Note that system interconnect masters can include masters in the FPGA accessing the FPGA-to-HPS bridge.

If a correctable ECC error occurs, the ECC corrects the read data in parallel to asserting a correctable error signal on the AXI bus. If an uncorrectable error occurs in the L2 cache, the uncorrected data remains in the L2 cache and an AXI slave error (SLVERR) is sent to the L1 memory system. In addition, interrupts can be enabled for correctable and uncorrectable ECC errors through the GIC.

Related Information

[System Manager](#) on page 6-1

For more information about SEU errors, refer to the *System Manager* chapter.

L2 Cache Parity

Because the L2 data RAM is ECC-protected, parity checking on the data RAM is not required. However, because the tag RAM is not ECC protected, it requires parity checking. Because parity cannot be configured independently, parity checking for both the data RAM and tag RAM must be enabled.

Ideally, parity should be enabled before the L2 cache is enabled. If the cache is already enabled, you must clean the cache and disable it before parity is enabled. After enabling parity, the cache is invalidated and enabled. To enable parity:

1. Set the `Parity_on` bit in the L2 Auxiliary Control register.
2. Invalidate the L2 cache through the Cache Maintenance Operations registers.
3. Enable the cache through the `L2_Cache_enable` bit of the L2 Control register.

Note: If you would like the parity errors to be reported you must enable the parity interrupts in the L2 Interrupt Mask register along with the corresponding interrupts in the general interrupt controller (GIC).

Refer to the Arm Infocenter website for more information regarding L2 cache registers and programming.

Parity Error Handling

If a parity error occurs in the tag or data RAM during AXI read transactions, a SLVERR response is reported through the event bus and interrupt signals. If a parity error occurs on tag or data RAM during AXI write transactions, a SLVERR response is reported back through a SLVERRINTR interrupt signal. For cache maintenance operations, if a parity error occurs on tag or data RAM, the error is reported back

through the interrupt lines only. In addition, the L2 Cache cannot refill a line from external memory due to a parity error.

Related Information

[Arm Infocenter](#)

L2 Cache Lockdown Capabilities

The L2 cache has three methods to lock data in the cache RAMs:

- Lockdown by line—Used to lock lines in the cache. This is commonly used for loading critical sections of software into the cache temporarily.
- Lockdown by way—Allows any or all of the eight cache ways to be locked. This is commonly used for loading critical data or code into the cache.
- Lockdown by master—Allows cache ways to be dedicated to a single master port. This allows a large cache to look like smaller caches to multiple master ports. The L2 cache can be mastered by CPU0, CPU1, or the six ACP masters, for a total of eight possible master ports.

Related Information

[Arm Infocenter](#)

For more information about L2 cache lockdown capabilities, refer to “Cache operation” in the *Functional Overview* chapter of the *CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual*, available on the Arm Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 10-12: L2 Cache Events

Event	Description
CO	Eviction (cast out) of a line from the L2 cache.
DRHIT	Data read hit in the L2 cache.
DRREQ	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
DWHIT	Data write hit in the L2 cache.
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.

Event	Description
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONF0	Speculative read confirmed in slave port S0.
SRCONF1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

[Arm Infocenter](#)

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the Arm Infocenter website.

L2 Cache Address Filtering

The L2 cache can access either the system interconnect fabric or the SDRAM. The L2 cache address filtering determines how much address space is allocated to the HPS-to-FPGA bridge and how much is allocated to SDRAM, depending on the configuration of the memory management unit.

Related Information

- [Cortex-A9 MPU Subsystem with System Interconnect](#) on page 10-2
- [Memory Management Unit](#) on page 10-9
Information about how the address space is set based on L2 cache address filtering.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

CPU Prefetch

The Cortex-A9 performs instruction and data prefetches regardless of the state of the MMU.

A prefetch occurs when any address that is 4 KB above the current instruction pointer is accessed. The system has been designed to ensure that the system bus does not lock on prefetches. Any prefetches to unmapped memory space produce a decode error on the system interconnect.

Debugging Modules

The MPU subsystem includes debugging resources through Arm CoreSight on-chip debugging and trace. The following functionality is included:

- Individual program trace for each processor
- Event trace for the Cortex-A9 MPCore
- Cross triggering between processors and other HPS debugging features

Program Trace

Each processor has an independent program trace monitor (PTM) that provides real-time instruction flow trace. The PTM is compatible with a number of third-party debugging tools.

The PTM provides trace data in a highly compressed format. The trace data includes tags for specific points in the program execution flow, called waypoints. Waypoints are specific events or changes in the program flow.

The PTM recognizes and tags the waypoints listed in [Table 10-13](#).

Table 10-13: Waypoints Supported by the PTM

Type	Additional Waypoint Information
Indirect branches	Target address and condition code
Direct branches	Condition code
Instruction barrier instructions	—
Exceptions	Location where the exception occurred
Changes in processor instruction set state	—

Type	Additional Waypoint Information
Changes in processor security state	—
Context ID changes	—
Entry to and return from debug state when Halting debug mode is enabled	—

The PTM optionally provides additional information for waypoints, including the following:

- Processor cycle count between waypoints
- Global timestamp values
- Target addresses for direct branches

Related Information

- [CoreSight Debug and Trace](#) on page 11-1
- [Arm Infocenter](#)

For more information about the PTM, refer to the CoreSight PTM-A9 Technical Reference Manual, available on the Arm Infocenter website.

Event Trace

Events from each processor can be used as inputs to the PTM. The PTM can use these events as trace and trigger conditions.

Related Information

- [Performance Monitoring Unit](#) on page 10-12
- [Arm Infocenter](#)

For more information about the trigger and trace capabilities, refer to the CoreSight PTM-A9 Technical Reference Manual, Revision r1p0, available on the Arm Infocenter website.

Cross-Triggering

The PTM can export trigger events and perform actions on trigger inputs. The cross-trigger signals interface with other HPS debugging components including the FPGA fabric. Also, a breakpoint in one processor can trigger a break in the other.

Related Information

[CoreSight Debug and Trace](#) on page 11-1

For detailed information about cross-triggering and about debugging hardware in the MPU, refer to the *CoreSight Debug and Trace* chapter.

Clocks

Four synchronous clocks and two debug clocks are provided to the MPU subsystem.

Table 10-14: MPU Subsystem Clocks

System Clock Name	Use
mpu_clk	Main clock for the MPU subsystem
mpu_periph_clk	Clock for peripherals inside the MPU subsystem
mpu_l2_ram_clk	Clock for the L2 cache and Accelerator Coherency Port (ACP) ID mapper
l4_mp_clk	Clock for the ACP ID mapper control slave
dbg_at_clk	Trace bus clock
dbg_clk	Debug clock

Related Information

[Clock Manager](#) on page 3-1

Cortex-A9 MPU Subsystem Register Implementation

The following configurations are available through registers in the Cortex-A9 subsystem:

- All processor-related controls, including the MMU and L1 caches, are controlled using the Coprocessor 15 (CP15) registers of each individual processor.
- All SCU registers, including control for the timers and GIC, are memory mapped.
- All L2 cache registers are memory-mapped.

Related Information

[Arm Infocenter](#)

For detailed definitions of the registers for the Cortex-A9 MPU subsystem, refer to the Cortex-A9 MPCore Technical Reference Manual, Revision r3p0 and the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision r3p3, available on the Arm Infocenter website.

Cortex-A9 MPU Subsystem Address Map

The Cortex-A9 MPU subsystem registers reside within the address range from 0xFFFFEC000 to 0xFFFFEFFF.

Table 10-15: MPU Module Address Range

Module Instance	Start Address	End Address
MPU	0xFFFFEC000	0xFFFFEFFF

Table 10-16: Cortex-A9 MPU Submodule Register Space

Submodule Instance	Description	Start Address	End Address
SCU	This address space is allocated for the Snoop Control Unit registers.	0xFFFFEC000	0xFFFFEC0FF
GIC	This address space is allocated for the Generic Interrupt Controller (GIC) registers.	0xFFFFEC100	0xFFFFEC1FF
Global Timer	This address space is allocated for the Global Timer registers.	0xFFFFC200	0xFFFFEC2FF
Reserved	This address space is reserved.	0xFFFFEC300	0xFFFFEC5FF
Private Timers and Watchdog Timers	This is the address space is allocated for private timer and watchdog timer registers.	0xFFFFEC600	0xFFFFEC6FF
Reserved	This address space is reserved. Note: Any access to this region causes a SLVERR abort exception.	0xFFFFEC700	0xFFFFEC7FF
Interrupt Distributor	This address space is allocated for the interrupt distributor registers.	0xFFFFED000	0xFFFFEDFFF
Reserved	This address space is reserved.	0xFFFFEE000	0xFFFFEFFF

Related Information

Cortex-A9 MPCore Technical Reference Manual

For more information about the use of the MPU address space, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the Arm Infocenter website.

L2 Cache Controller Address Map

The register space for the L2 cache controller ranges from 0xFFEF000 to 0xFFEFFFFF.

Table 10-17: MPU L2 Cache Controller Address Range

Module Instance	Start Address	End Address
MPUL2	0xFFEF000	0xFFEFFFFF

Table 10-18: MPU L2 Cache Controller Register Range

Register Group	Description	Start Address	End Address
Cache ID and Cache Type	This address space is allocated for the cache ID and cache type registers.	0xFFEF000	0xFFEF0FF
Control	This is the address space for the cache control registers.	0xFFEF100	0xFFEF1FF
Interrupt/Counter Control	This address space is allocated for the Interrupt/Counter control registers.	0xFFEF200	0xFFEF2FF
Reserved	This address space is reserved.	0xFFEF300	0xFFEF6FF
Cache Maintenance Operations	This is the address space is allocated for the cache maintenance operation registers.	0xFFEF700	0xFFEF7FF
Reserved	This address space is reserved.	0xFFEF800	0xFFEF8FF
Cache Lockdown	This address space is allocated for cache lockdown registers.	0xFFEF900	0xFFEF9FF
Reserved	This address space is reserved.	0xFFEFA00	0xFFEFBFF

Register Group	Description	Start Address	End Address
Address Filtering	This address space is allocated for address filtering registers.	0xFFFFEFC00	0xFFFFEFCFF
Reserved	This address space is reserved.	0xFFFFEFD00	0xFFFFEFFF
Debug, Prefetch, Power	This address space is allocated for debug, prefetch and power registers.	0xFFFFEFFF00	0xFFFFEFFFF

CoreSight systems provide all the infrastructure you require to debug, monitor, and optimize the performance of a complete HPS design. CoreSight technology addresses the requirement for a multicore debug and trace solution with high bandwidth for whole systems beyond the processor core.

CoreSight technology provides the following features:

- Cross-trigger support between SoC subsystems
- High data compression
- Multi-source trace in a single stream
- Standard programming models for standard tool support

The hard processor system (HPS) debug infrastructure provides visibility and control of the HPS modules, the Arm Cortex-A9 microprocessor unit (MPU) subsystem, and user logic implemented in the FPGA fabric. The debug system design incorporates Arm CoreSight components.

Details of the Arm CoreSight debug components can be viewed by clicking on the following related information links:

Features of CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate Program Trace Macrocell (PTM) for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP generation of triggers and system trace messages
- External trace interface through Trace Port Interface Unit (TPIU) for trace analysis tools
- Custom message injection through the System Trace Macrocell (STM) into the trace stream for delivery to a host debugger
- STM and PTM trace sources multiplexed into a single stream through the Trace Funnel
- Capability to route trace data to any slave accessible to the Embedded Trace Router (ETR) AXI master connected to the level 3 (L3) interconnect
- Capability for the following components to trigger each other through the embedded cross-trigger system:
 - Cortex-A9 PTM-0
 - Cortex-A9-A9 PTM-1
 - STM
 - Embedded Trace FIFO (ETF)
 - ETR
 - TPIU
 - csCross Trigger Interface (CTI)
 - FPGA-CTI
 - csCross Trigger Matrix (CTM)

CoreSight Debug and Trace Block Diagram and System Integration

Figure 11-1: HPS CoreSight Debug and Trace System Block Diagram

Functional Description of CoreSight Debug and Trace

Debug Access Port

The Debug Access Port (DAP) provides the necessary ports for a host debugger to connect to and communicate with the HPS through a JTAG interface connected to dedicated HPS pins that is independent of the JTAG for the FPGA. The JTAG interface provided with the DAP allows a host debugger to access various modules inside the HPS. Additionally, a debug monitor executing on either processor can access different HPS components by interfacing with the system Advanced Microcontroller Bus Architecture (AMBA) Advanced Peripheral Bus (APB) slave port of the DAP.

The system APB slave port occupies 2 MB of address space in the HPS. Both the JTAG port and system APB port have access to the debug APB master port of the DAP.

A host debugger can access any HPS memory-mapped resource in the system through the DAP system master port. Requests made over the DAP system master port are impacted by reads and writes to peripheral registers.

Note: The HPS JTAG interface does not support boundary scan tests (BST). To perform boundary scan testing on HPS I/Os, use the FPGA JTAG pins.

Related Information

Refer to the *CoreSight Components Technical Reference Manual* on the Arm Infocenter website.

System Trace Macrocell

The STM allows messages to be injected into the trace stream for delivery to the host debugger receiving the trace data. These messages can be sent through stimulus ports or the hardware EVENT interface. The STM allows these messages to be time stamped.

The STM provides an AMBA Advanced eXtensible Interface (AXI) slave interface used to create trace events. The interface can be accessed by the MPU subsystem, direct memory access (DMA) controller, and masters implemented as soft logic in the FPGA fabric through the FPGA-to-HPS bridge. The AXI slave interface supports three address segments, where each address segment is 16 MB and each segment supports up to 65536 channels. Each channel occupies 256 bytes of address space.

The STM also provides 32 hardware EVENT pins. The higher-order 28 pins (31:4) are connected to the FPGA fabric, allowing logic inside FPGA to insert messages into the trace stream. When the STM detects a rising edge on an EVENT pin, a message identifying the EVENT is inserted into the stream. The lower four EVENT pins (3:0) are connected to csCTI.

Trace Funnel

The Trace Funnel is used to combine multiple trace streams into one trace stream. There are three trace streams that use the following funnel ports:

Table 11-1: Trace Stream Connections

Funnel Port	Description
0	The trace stream coming from PTM connected to CPU0 uses this port.
1	The trace stream coming from PTM connected to CPU1 uses this port.
2	Not connected.
3	The trace stream coming from STM uses this port.
4 .. 7	Not connected.

Related Information

Refer to the *CoreSight Components Technical Reference Manual* on the Arm Infocenter website.
- [Program Trace Macrocell](#) on page 11-11

CoreSight Trace Memory Controller

The CoreSight Trace Memory Controller (TMC) has three possible configurations:

- Embedded Trace FIFO (ETF)
- Embedded Trace Router (ETR)
- Embedded Trace Buffer (ETB)

ETB is not used in this device.

Related Information

[Arm Infocenter](#)

For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the Arm Infocenter website.

Embedded Trace FIFO

The Trace Funnel output is sent to the ETF. The ETF is used as an elastic buffer between trace generators (STM, PTM) and trace destinations. The ETF stores up to 32 KB of trace data in the on-chip trace RAM.

Related Information**[Arm Infocenter](#)**

For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the Arm Infocenter website.

Embedded Trace Router

The ETR can route trace data to the HPS on-chip RAM, the HPS SDRAM, and any memory in the FPGA fabric connected to the HPS-to-FPGA bridge. The ETR receives trace data from the AMBA Trace Bus Replicator. By default, the buffer to receive the trace data resides in SDRAM at offset 0x00100000 and is 32 KB. You can override this default configuration by programming registers in the ETR.

Related Information

- **[HPS-FPGA Bridges](#)** on page 9-1
- **[CoreSight Debug and Trace Programming Model](#)** on page 11-16
- **[Arm Infocenter](#)**

For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the Arm Infocenter website.

AMBA Trace Bus Replicator

The AMBA Trace Bus Replicator broadcasts trace data from the ETF to the ETR and TPIU.

Related Information**[Arm Infocenter](#)**

Refer to the *CoreSight Components Technical Reference Manual* on the Arm Infocenter website.

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and an off-chip trace port. The TPIU receives trace data from the Trace Bus Replicator (Replicator) and drives the trace data to a trace port analyzer.

The trace output from the TPIU is software programmable and can be set to either 8 or 32 bits wide. The trace output is routed to an 8-bit HPS I/O interface and a 32-bit interface to the FPGA fabric. The trace data sent to the FPGA fabric can be transported off-chip using available serializer/deserializer (SERDES) resources in the FPGA.

Related Information**[Arm Infocenter](#)**

Refer to the *CoreSight Components Technical Reference Manual* on the Arm Infocenter website.

Embedded Cross Trigger System

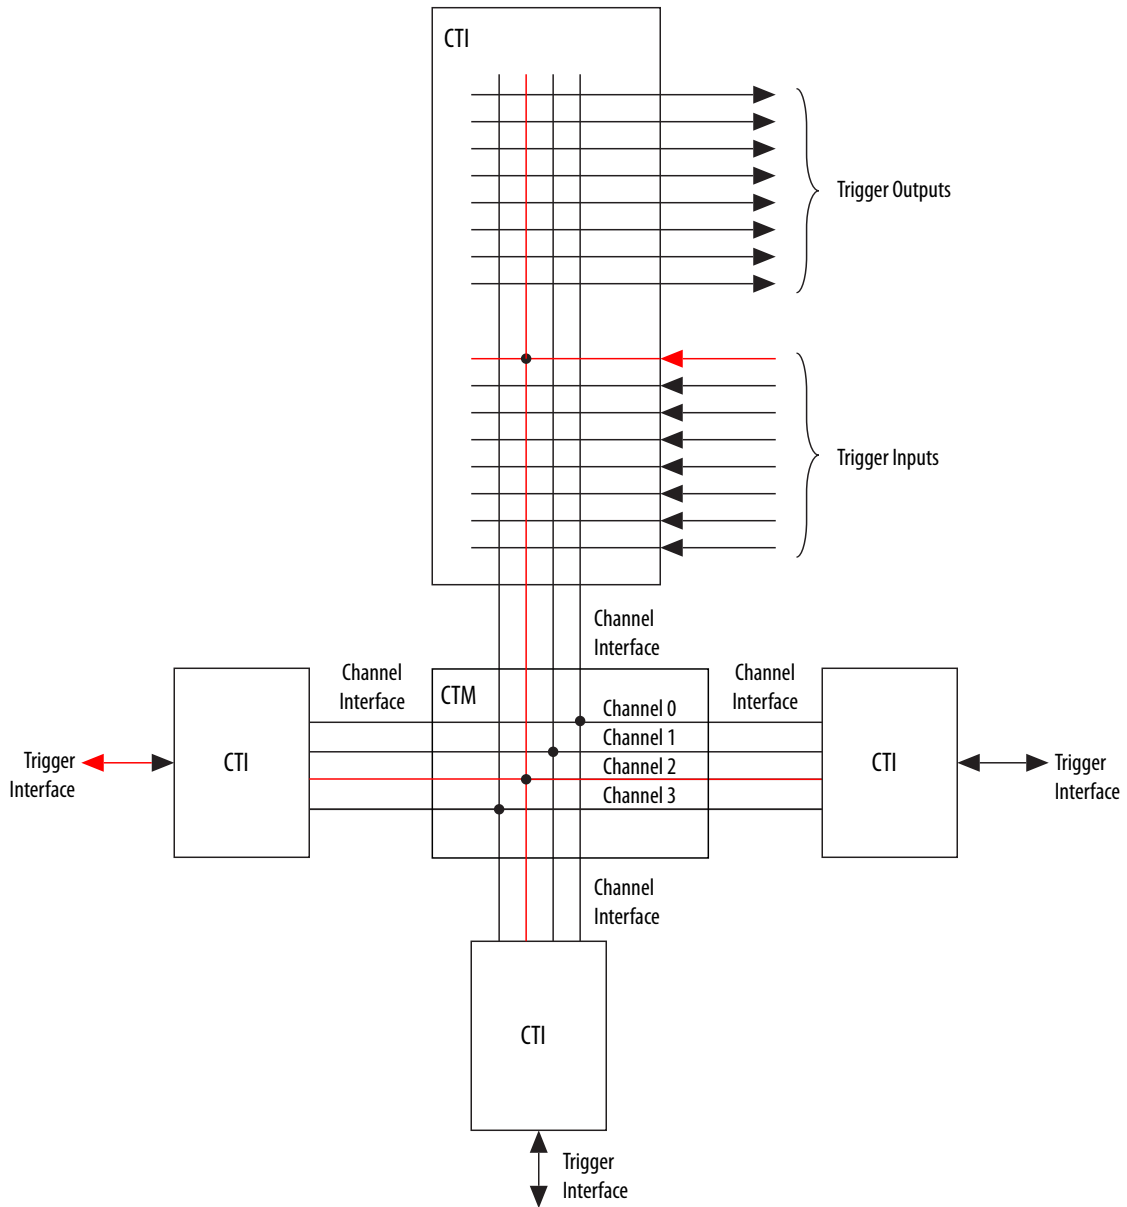

The ECT system provides a mechanism for the components listed in "Features of the CoreSight Debug and Trace" to trigger each other. The ECT consists of the following modules:

- Cross Trigger Interface (CTI)
- Cross Trigger Matrix (CTM)

Figure 11-2: Generic ECT System

The following figure shows an example of how CTIs and CTMs are used in a generic ECT setup. Though the signal travels through channel 2, it only enters and exits through trigger inputs and outputs you configure.

Note: The red line depicts an trigger input to one CTI generating a trigger output in another CTI.

Related Information

- [Cross Trigger Interface](#) on page 11-8
- [Features of CoreSight Debug and Trace](#) on page 11-2
- [Cross Trigger Matrix](#) on page 11-8

Cross Trigger Interface

CTIs allow trigger sources and sinks to interface with the ECT. Each CTI supports up to eight trigger inputs and eight trigger outputs, and is connected to a CTM. **Figure 11-3** shows the relationship of trigger inputs, trigger outputs, and CTM channels of a CTI.

Figure 11-3: CTI Connections

The following figure shows the eight potential trigger input and trigger output connections that are supported.

The HPS debug system contains the following CTIs:

- csCTI—performs cross triggering between the STM, ETF, ETR, and TPIU.
- FPGA-CTI—exposes the cross-triggering system to the FPGA fabric.
- CTI-0 and CTI-1—reside in the MPU debug subsystem. Each CTI is associated with a processor and the processor's PTM.

Cross Trigger Matrix

A CTM is a transport mechanism for triggers traveling from one CTI to one or more CTIs or CTMs. The HPS contains two CTMs. One CTM connects csCTI and FPGA-CTI; the other connects CTI-0 and CTI-1. The two CTMs are connected together, allowing triggers to be transmitted between the MPU debug subsystem, the debug system, and the FPGA fabric.

Each CTM has four ports and each port has four channels. Each CTM port can be connected to a CTI or another CTM.

Figure 11-4: CTM Channel Structure

The following figure shows the structure of a CTM channel. Paths inside the CTM are purely combinational.

Figure 11-5: CTI Trigger Connections

Each CTI trigger input can be connected through a CTM to one or more trigger outputs under control by a debugger. The following figure shows an example of CTI trigger connections.

Note: The red lines depict the impact one trigger input can have on the entire system.

Related Information

[Arm Infocenter](#)

Refer to the *CoreSight Components Technical Reference Manual* on the Arm Infocenter website.

Program Trace Macrocell

The PTM performs real-time program flow instruction tracing and provides a variety of filters and triggers that can be used to trace specific portions of code.

The HPS contains two PTMs. Each PTM is paired with a processor and CTI. Trace data generated from the PTM can be transmitted off-chip using HPS pins, or to the FPGA fabric, where it can be pre-processed and transmitted off-chip using high-speed FPGA pins.

Related Information

[Arm Infocenter](#)

For more information, refer to the *CoreSight PTM-A9 Technical Reference Manual*.

HPS Debug APB Interface

The HPS can extend the CoreSight debug control bus into the FPGA fabric. The debug interface is an APB-compatible interface with built-in clock crossing.

Related Information

- [FPGA Interface](#) on page 11-11
- [HPS Component Interfaces](#) on page 29-1

FPGA Interface

The following components connect to the FPGA fabric. This section lists the signals from the debug system to the FPGA.

DAP

The DAP uses the system APB port to connect to the FPGA.

Table 11-2: DAP

The following table shows the signal description between DAP and FPGA.

Signal	Description
h2f_dbg_apb_PADDR	Address bus to system APB port, when PADDR
h2f_dbg_apb_PADDR31	Address bus to system APB port, when PADDR31
h2f_dbg_apb_PENABLE	Enable signal from system APB port
h2f_dbg_apb_PRDATA[32]	32-bit system APB port read data bus
h2f_dbg_apb_PREADY	Ready signal to system APB port
h2f_dbg_apb_PSEL	Select signal from system APB port
h2f_dbg_apb_PSLVERR	Error signal to system APB port
h2f_dbg_apb_PWDATA[32]	32-bit system APB port write data bus

Signal	Description
h2f_dbg_apb_PWRITE	Select whether read or write to system APB port <ul style="list-style-type: none"> 0 - System APB port read from DAP 1 - System APB Port write to DAP

STM

The STM has 28 event pins, `f2h_stm_hw_events[28]`, for FPGA to trigger events to STM.

FPGA-CTI

The FPGA-CTI allows the FPGA to send and receive triggers from the debug system.

Table 11-3: FPGA-CTI Signal Description Table

The following table lists the signal descriptions between the FPGA-CTI and FPGA.

Signal	Description
h2f_cti_trig_in[8]	Trigger input from FPGA
h2f_cti_trig_in_ack[8]	ACK signal to FPGA
h2f_cti_trig_out[8]	Trigger output to FPGA
h2f_cti_trig_out_ack[8]	ACK signal from FPGA
h2f_cti_clk	Clock input from FPGA
h2f_cti_fpga_clk_en	Clock enable driven by FPGA
h2f_cti_asicctl[8]	Signal from FPGA

Related Information

[Arm Infocenter](#)

TPIU

Figure 11-6: Trace Clock and Trace Data Width

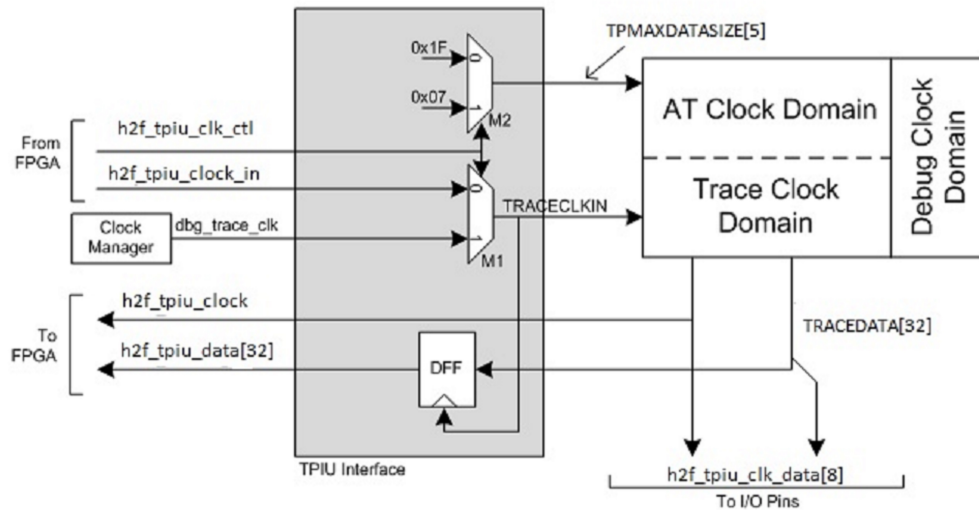

Table 11-4: TPIU Signals

The following table lists the signal descriptions between the TPIU and FPGA.

Signal	Description
h2f_tpiu_clk_ctl	<p>Selects whether trace data is captured using the internal TPIU clock, which is the <code>dbg_trace_clk</code> signal from the clock manager; or an external clock provided as an input to the TPIU from the FPGA.</p> <p>0 - use <code>h2f_tpiu_clock_in</code></p> <p>1 - use internal clock</p> <p>Note: When the FPGA is powered down or not configured the TPIU uses the internal clock.</p>
h2f_tpiu_data[32]	<p>32 bit trace data bus to the FPGA. Trace data changes on both edges of <code>h2f_tpiu_clock</code>.</p> <p>Note: When the FPGA is powered down or not configured, the TPIU sends the lower 8-bits trace data to I/Os.</p>
h2f_tpiu_clock_in	Clock from the FPGA used to capture trace data.

Signal	Description
h2f_tpiu_clock	Clock output from TPIU

Debug Clocks

Table 11-5: CoreSight Clocks

Arm Clock Name	Clock Source	HPS Clock Signal Name	Description
ATCLK	Clock manager	dbg_at_clk	Trace bus clock.
CTICK (for csCTI)	Clock manager	dbg_at_clk	Cross trigger interface clock for csCTI. It can be synchronous or asynchronous to CTMCLK.
CTICK (for FPGA-CTI)	FPGA fabric	fpga_cti_clk	Cross trigger interface clock for FPGA-CTI.
CTICK (for CTI-0 and CTI-1)	Clock manager	mpu_clk	Cross trigger interface clock for CTI-0 and CTI-1. It can be synchronous or asynchronous to CTMCLK.
CTMCLK (for csCTM)	Clock manager	dbg_clk	Cross trigger matrix clock for csCTM. It can be synchronous or asynchronous to CTICK.
CTMCLK (for CTM)	Clock manager	mpu_clk	Cross trigger matrix clock for CTM. It can be synchronous or asynchronous to CTICK.
DAPCLK	Clock manager	dbg_clk	DAP internal clock. It must be equivalent to PCLKDBG. dbg_clk must be at least twice as fast as the JTAG clock.
PCLKDBG	Clock manager	dbg_clk	Debug APB (DAPB) clock.
HCLK	Clock manager	dbg_clk	Used by the AHB-Lite master inside the DAP. It is asynchronous to DAPCLK. In the HPS, the AHB-Lite port uses same clock as DAPCLK.

Arm Clock Name	Clock Source	HPS Clock Signal Name	Description
PCLKSYS	Clock manager	l4_mp_clk	Used by the APB slave port inside the DAP. It is asynchronous to DAPCLK.
SWCLKTCK	JTAG interface FPGA fabric Note: There are two clock sources.	dap_tck tpiu_traceclk Note: There are two signal names.	The SWJ-DP clock driven by the external debugger through either the JTAG interface or the FPGA fabric. It is asynchronous to DAPCLK. When through the JTAG interface, this clock is the same as TCK of the JTAG interface.
TRACECLKIN	Clock manager	dbg_trace_clk	TPIU trace clock input. It is asynchronous to ATCLK. In the HPS, this clock can come from the clock manager or the FPGA fabric.

Related Information

[Arm Infocenter](#)

For more information about the CoreSight port names, refer to the *CoreSight Technology System Design Guide*.

Debug Resets

The CoreSight system uses several resets.

Table 11-6: CoreSight Resets

Arm Reset Name	Clock Source	HPS Reset Signal Name	Description
ATRESETn	Reset manager	dbg_rst_n	Trace bus reset. It resets all registers in the ATCLK domain.
nCTIRESET	Reset manager	dbg_rst_n	CTI reset signal. It resets all registers in the CTICLK domain. In the HPS, there are four instances of CTI. All four use the same reset signal.
DAPRESETn	Reset manager	dbg_rst_n	DAP internal reset. It is connected to PRESETDBGn.

Arm Reset Name	Clock Source	HPS Reset Signal Name	Description
PRESETDBGn	Reset manager	dbg_rst_n	Debug APB reset. Resets all registers clocked by PCLKDBG.
HRESETn	Reset manager	sys_dbg_rst_n	SoC-provided reset signal that resets all of the AMBA on-chip interconnect. Use this signal to reset the DAP AHB-Lite master port.
PRESETSYSn	Reset manager	sys_dbg_rst_n	Resets system APB slave port of DAP.
nCTMRESET	Reset manager	dbg_rst_n	CTM reset signal. It resets all signals clocked by CTMCLK.
nPOTRST	Reset manager	tap_cold_rst_n	True power on reset signal to the DAP SWJ-DP. It must only reset at power-on.
nTRST	JTAG interface	nTRST pin	Resets the DAP TAP controller inside the SWJ-DP. This signal is driven by the host using the JTAG connector.
TRESETn	Reset manager	dbg_rst_n	Reset signal for TPIU. Resets all registers in the TRACECLKIN domain.

The ETR stall enable field (`etrstallen`) of the `ctrl` register in the reset manager controls whether the ETR is requested to stall its AXI master interface to the L3 interconnect before a warm or debug reset.

The level 4 (L4) watchdog timers can be paused during debugging to prevent reset while the processor is stopped at a breakpoint.

CoreSight Debug and Trace Programming Model

This section describes programming model details specific to the device implementation of the Arm CoreSight technology.

The debug components can be configured to cause triggers when certain events occur. For example, soft logic in the FPGA fabric can signal an event which triggers an STM message injection into the trace stream.

Related Information

[Arm Infocenter](#)

Programming interface details of each CoreSight component.

CoreSight Component Address

CoreSight components are configured through memory-mapped registers, located at offsets relative to the CoreSight component base address. CoreSight component base addresses are accessible through the component address table in the DAP ROM.

Table 11-7: CoreSight Component Address Table

The following table is located in the ROM table portion of the DAP.

ROM Entry	Offset[30:12]	Description
0x0	0x00001	ETF Component Base Address
0x1	0x00002	CTI Component Base Address
0x2	0x00003	TPIU Component Base Address
0x3	0x00004	Trace Funnel Component Base Address
0x4	0x00005	STM Component Base Address
0x5	0x00006	ETR Component Base Address
0x6	0x00007	FPGA-CTI Component Base Address
0x7	0x00100	A9 ROM
0x8	0x00080	FPGA ROM
0x9	0x00000	End of ROM

A host debugger can access this table at 0x80000000 through the DAP. HPS masters can access this ROM at 0xFF000000. Registers for a particular CoreSight component are accessed by adding the register offset to the CoreSight component base address, and adding that total to the base address of the ROM table.

The base address of the ROM table is different when accessed from the debugger (at 0x8000_0000) than when accessed from any HPS master (at 0xFF000000). For example, the CTI output enable (CTIOUTEN) register, CTIOUTEN[2] at offset 0xA8, can be accessed by the host debugger at 0x800020A8. To derive that value, add the host debugger access address to the ROM table of 0x80000000, to the CTI component base address of 0x00002000, to the CTIOUTEN[2] register offset of 0xA8.

STM Channels

The STM AXI slave is connected to the MPU, DMA, and FPGA-to-HPS bridge masters. Each master has up to 65536 channels where each channel occupies 256 bytes of address space, for a total of 16 MB per master. The HPS address map allocates 48 MB of consecutive address space to the STM AXI slave port, divided in three 16 MB segments.

Table 11-8: STM AXI Slave Port Address Allocation

Segment	Start Address	End Address
0	0xFC000000	0xFCFFFFFF
1	0xFD000000	0xFDFFFFFFF
2	0xFE000000	0xFEFFFFFF

Each of the three masters can access any one of the three address segments. Your software design determines which master uses which segment, based on the value of bits 24 and 25 in the write address, `AWADDRS[25:24]`. Software must restrict each master to use only one of the three segments.

Table 11-9: STM AXI Address Fields

STM receives trace data over an AXI slave port. This table contains a list of signals associated with this interface.

AXI Signal Fields	Description
<code>AWADDRS[7:0]</code>	These bits index the 256 bytes of the stimulus port.
<code>AWADDRS[23:8]</code>	These bits identify the 65536 stimulus ports associated with a master.
<code>AWADDRS[25:24]</code>	These bits identify the three masters. Only 0, 1, and 2 are valid values.
<code>AWADDRS[31:26]</code>	Always 0x3F. Bits 24 to 31 combine to access 0xFC000000 through 0xFEFFFFFF.

Each STM message contains a master ID that tells the host debugger which master is associated with the message. The STM master ID is determined by combining a portion of the `AWADDRS` signal and the `AWPROT` protection bit. In the following table, `MasterID[6]` identifies the

Table 11-10: STM Master ID Calculation

Master ID Bits	AXI Signal Bits	Notes
Master ID[5:0]	AWADDRS[29:24]	The lowest two bits are sufficient to determine which master, but CoreSight uses a six-bit master ID.
Master ID[6]	AWPROT[1]	0 indicates a secure master; 1 indicates a nonsecure master.

In addition to access through STM channels, the higher-order 28 (31:4) of the 32 event signals are attached to the FPGA through the FPGA-CTI. These event signals allow the FPGA fabric to send additional messages using the STM.

CTI Trigger Connections to Outside the Debug System

The following CTIs in the HPS debug system connect to outside the debug system:

- csCTI
- FPGA-CTI

csCTI

This section lists the trigger input, output, and output acknowledge pin connections implemented for csCTI in the debug system. The trigger input acknowledge signals are not connected to pins.

Table 11-11: csCTI Trigger Input Signals

The following table lists the trigger input pin connections implemented for csCTI.

Pin Number	Signal	Source
7	ASYNCOUT	STM
6	TRIGOUTHETE	STM
5	TRIGOUTSW	STM
4	TRIGOUTSPTE	STM
3	ACQCOMP	ETR
2	FULL	ETR

Pin Number	Signal	Source
1	ACQCOMP	ETF
0	FULL	ETF

Table 11-12: csCTI Trigger Output Signals

The following table lists the trigger output pin connections implemented for csCTI.

Pin Number	Signal	Destination
7	TRIGIN	ETF
6	FLUSHIN	ETF
5	HWEVENTS [3 : 2]	STM
4	HWEVENTS [1 : 0]	STM
3	TRIGIN	TPIU
2	FLUSHIN	TPIU
1	TRIGIN	ETR
0	FLUSHIN	ETR

Table 11-13: csCTI Trigger Output Acknowledge Signals

The following table lists the trigger output pin acknowledge connections implemented for csCTI.

Pin Number	Signal	Source
7	0	—
6	0	—
5	0	—
4	0	—
3	TRIGINACK	TPIU
2	FLUSHINACK	TPIU
1	0	—
0	0	—

FPGA-CTI

FPGA-CTI connects the debug system to the FPGA fabric. FPGA-CTI has all of its triggers available to the FPGA fabric.

Related Information

[Configuring Embedded Cross-Trigger Connections](#) on page 11-21

For more information about the triggers, refer to the "Configuring Embedded Cross-Trigger Connections" chapter.

Configuring Embedded Cross-Trigger Connections

CTI interfaces are programmable through a memory-mapped register interface.

The specific registers are described in the *CoreSight Components Technical Reference Manual*, which you can download from the Arm Infocenter.

To access registers in any CoreSight component through the debugger, the register offsets must be added to the CoreSight component's base address. That combined value must then be added to the address at which the ROM table is visible to the debugger (0x80000000).

Each CTI has two interfaces, the trigger interface and the channel interface. The trigger interface is the interface between the CTI and other components. It has eight trigger signals, which are hardwired to other components. The channel interface is the interface between a CTI and its CTM, with four bidirectional channels. The mapping of trigger interface to channel interface (and vice versa) in a CTI is dynamically configured. You can enable or disable each CTI trigger output and CTI trigger input connection individually.

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, and multiple-to-multiple.

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in the csCTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in the csCTI.

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. The csCTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in the csCTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

Related Information

- [Coresight Component Address](#) on page 11-17
- [Arm Infocenter](#)
For more information about the cross-trigger interface

Configuring Trigger Input 0

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, or multiple-to-multiple.

Triggering a Flush of Trace Data to the TPIU

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in csCTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in csCTI.

Triggering an STM message

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. csCTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in csCTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

Triggering a Breakpoint on CPU 1

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the external debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

CoreSight Debug and Trace Address Map and Register Definitions

The address map and register definitions for CoreSight Debug and Trace consist of the following regions:

SDRAM Controller Subsystem 12

2020.01.13

cv_5v4

Subscribe

Send Feedback

The hard processor system (HPS) SDRAM controller subsystem provides efficient access to external SDRAM for the Arm Cortex-A9 microprocessor unit (MPU) subsystem, the level 3 (L3) interconnect, and the FPGA fabric.

The SDRAM controller provides an interface between the FPGA fabric and HPS. The interface accepts Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) and Avalon[®] Memory-Mapped (Avalon-MM) transactions, converts those commands to the correct commands for the SDRAM, and manages the details of the SDRAM access.

Features of the SDRAM Controller Subsystem

The SDRAM controller subsystem offers programming flexibility, port and bus configurability, error correction, and power management.

- Support for double data rate 2 (DDR2), DDR3, and low-power DDR2 (LPDDR2) SDRAM
- Flexible row and column addressing with the ability to support up to 4 Gb of memory per chip select
- Optional 8-bit integrated error correction code (ECC) for 16- and 32-bit data widths⁽²⁵⁾
- User-configurable memory width of 8, 16, 16+ECC, 32, 32+ECC
- User-configurable timing parameters
- Two chip selects (DDR2 and DDR3)
- Command reordering (look-ahead bank management)
- Data reordering (out of order transactions)
- User-controllable bank policy on a per port basis for either closed page or conditional open page accesses
- User-configurable priority support with both absolute and weighted round-robin scheduling
- Flexible FPGA fabric interface with up to 6 ports that can be combined for a data width up to 256 bits using Avalon-MM and AXI interfaces
- Power management supporting self refresh, partial array self refresh (PASR), power down, and LPDDR2 deep power down

⁽²⁵⁾ The level of ECC support is package dependent.

SDRAM Controller Subsystem Block Diagram

The SDRAM controller subsystem connects to the MPU subsystem, the L3 interconnect, and the FPGA fabric. The memory interface consists of the SDRAM controller, the physical layer (PHY), control and status registers (CSRs), and their associated interfaces.

Figure 12-1: SDRAM Controller Subsystem High-Level Block Diagram

SDRAM Controller

The SDRAM controller provides high performance data access and run-time programmability. The controller reorders data to reduce row conflicts and bus turn-around time by grouping read and write transactions together, allowing for efficient traffic patterns and reduced latency.

The SDRAM controller consists of a multiport front end (MPFE) and a single-port controller. The MPFE provides multiple independent interfaces to the single-port controller. The single-port controller communicates with and manages each external memory device.

The MPFE FPGA-to-HPS SDRAM interface port has an asynchronous FIFO buffer followed by a synchronous FIFO buffer. Both the asynchronous and synchronous FIFO buffers have a read and write data FIFO depth of 8, and a command FIFO depth of 4. The MPU subsystem 64-bit AXI port and L3 interconnect 32-bit AXI port have asynchronous FIFO buffers with read and write data FIFO depth of 8, and command FIFO depth of 4.

DDR PHY

The DDR PHY provides a physical layer interface for read and write memory operations between the memory controller and memory devices. The DDR PHY has dataflow components, control components, and calibration logic that handle the calibration for the SDRAM interface timing.

	2048 (2 Gb) - S2 ⁽²⁷⁾	11	2	15	2048	256
	2048 (2 Gb) - S4 ⁽²⁸⁾	11	3	14	2048	256
	4096 (4 Gb)	12	3	14	4096	512

SDRAM Controller Subsystem Interfaces

MPU Subsystem Interface

The SDRAM controller connects to the MPU subsystem with a dedicated 64-bit AXI interface, operating on the `mpu_12_ram_clk` clock domain.

L3 Interconnect Interface

The SDRAM controller interfaces to the L3 interconnect with a dedicated 32-bit AXI interface, operating on the `l3_main_clk` clock domain.

Related Information

[System Interconnect](#) on page 8-1

⁽²⁶⁾ For all memory types shown in this table, the DQ width is 8.

⁽²⁷⁾ S2 signifies a 2n prefetch size

⁽²⁸⁾ S4 signifies a 4n prefetch size

CSR Interface

The CSR interface connects to the level 4 (L4) bus and operates on the `l4_sp_clk` clock domain. The MPU subsystem uses the CSR interface to configure the controller and PHY, for example setting the memory timing parameter values or placing the memory in a low power state. The CSR interface also provides access to the status registers in the controller and PHY.

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface provides masters implemented in the FPGA fabric access to the SDRAM controller subsystem in the HPS. The interface has three port types that are used to construct the following AXI or Avalon-MM interfaces:

- Command ports—issue read and write commands, and for receive write acknowledge responses
- 64-bit read data ports—receive data returned from a memory read
- 64-bit write data ports—transmit write data

The FPGA-to-HPS SDRAM interface supports six command ports, allowing up to six Avalon-MM interfaces or three AXI interfaces. Each command port can be used to implement either a read or write command port for AXI, or be used as part of an Avalon-MM interface. The AXI and Avalon-MM interfaces can be configured to support 32-, 64-, 128-, and 256-bit data.

Table 12-2: FPGA-to-HPS SDRAM Controller Port Types

Port Type	Available Number of Ports
Command	6
64-bit read data	4
64-bit write data	4

The FPGA-to-HPS SDRAM controller interface can be configured with the following characteristics:

- Avalon-MM interfaces and AXI interfaces can be mixed and matched as required by the fabric logic, within the bounds of the number of ports provided to the fabric.
- Because the AXI protocol allows simultaneous read and write commands to be issued, two SDRAM control ports are required to form an AXI interface.
- Because the data ports are natively 64-bit, they must be combined if wider data paths are required for the interface.
- Each Avalon-MM or AXI interface of the FPGA-to-HPS SDRAM interface operates on an independent clock domain.
- The FPGA-to-HPS SDRAM interfaces are configured during FPGA configuration.

The following table shows the number of ports needed to configure different bus protocols, based on type and data width.

Table 12-3: FPGA-to-HPS SDRAM Port Utilization

Bus Protocol	Command Ports	Read Data Ports	Write Data Ports
32- or 64-bit AXI	2	1	1

Bus Protocol	Command Ports	Read Data Ports	Write Data Ports
128-bit AXI	2	2	2
256-bit AXI	2	4	4
32- or 64-bit Avalon-MM	1	1	1
128-bit Avalon-MM	1	2	2
256-bit Avalon-MM	1	4	4
32- or 64-bit Avalon-MM write-only	1	0	1
128-bit Avalon-MM write-only	1	0	2
256-bit Avalon-MM write-only	1	0	4
32- or 64-bit Avalon-MM read-only	1	1	0
128-bit Avalon-MM read-only	1	2	0
256-bit Avalon-MM read-only	1	4	0

Memory Controller Architecture

The SDRAM controller consists of an MPFE, a single-port controller, and an interface to the CSRs.

Figure 12-2: SDRAM Controller Block Diagram

Multi-Port Front End

The Multi-Port Front End (MPFE) is responsible for scheduling pending transactions from the configured interfaces and sending the scheduled memory transactions to the single-port controller. The MPFE handles all functions related to individual ports.

The MPFE consists of three primary sub-blocks.

Command Block

The command block accepts read and write transactions from the FPGA fabric and the HPS. When the command FIFO buffer is full, the command block applies backpressure by deasserting the ready signal. For each pending transaction, the command block calculates the next SDRAM burst needed to progress on that transaction. The command block schedules pending SDRAM burst commands based on the user-supplied configuration, available write data, and unallocated read data space.

Write Data Block

The write data block transmits data to the single-port controller. The write data block maintains write data FIFO buffers and clock boundary crossing for the write data. The write data block informs the command block of the amount of pending write data for each transaction so that the command block can calculate eligibility for the next SDRAM write burst.

Read Data Block

The read data block receives data from the single-port controller. Depending on the port state, the read data block either buffers the data in its internal buffer or passes the data straight to the clock boundary crossing FIFO buffer. The read data block reorders out-of-order data for Avalon-MM ports.

In order to prevent the read FIFO buffer from overflowing, the read data block informs the command block of the available buffer area so the command block can pace read transaction dispatch.

Single-Port Controller

The single-port logic is responsible for following actions:

- Queuing the pending SDRAM bursts
- Choosing the most efficient burst to send next
- Keeping the SDRAM pipeline full
- Ensuring all SDRAM timing parameters are met

Transactions passed to the single-port logic for a single page in SDRAM are guaranteed to be executed in order, but transactions can be reordered between pages. Each SDRAM burst read or write is converted to the appropriate Altera PHY interface (AFI) command to open a bank on the correct row for the transaction (if required), execute the read or write command, and precharge the bank (if required).

The single-port logic implements command reordering (looking ahead at the command sequence to see which banks can be put into the correct state to allow a read or write command to be executed) and data reordering (allowing data transactions to be dispatched even if the data transactions are executed in an order different than they were received from the multi-port logic).

The single-port controller consists of eight sub-modules.

Command Generator

The command generator accepts commands from the MPFE and from the internal ECC logic, and provides those commands to the timer bank pool.

Related Information

[Memory Controller Architecture](#) on page 12-6

For more information, refer to the SDRAM Controller Block diagram.

Timer Bank Pool

The timer bank pool is a parallel queue that operates with the arbiter to enable data reordering. The timer bank pool tracks incoming requests, ensures that all timing requirements are met, and, on receiving write-data-ready notifications from the write data buffer, passes the requests to the arbiter.

Related Information

[Memory Controller Architecture](#) on page 12-6

For more information, refer to the SDRAM Controller Block diagram.

Arbiter

The arbiter determines the order in which requests are passed to the memory device. When the arbiter receives a single request, that request is passed immediately. When multiple requests are received, the arbiter uses arbitration rules to determine the order to pass requests to the memory device.

Related Information

[Memory Controller Architecture](#) on page 12-6

For more information, refer to the SDRAM Controller Block diagram.

Rank Timer

The rank timer performs the following functions:

- Maintains rank-specific timing information
- Ensures that only four activates occur within a specified timing window
- Manages the read-to-write and write-to-read bus turnaround time
- Manages the time-to-activate delay between different banks

Related Information

[Memory Controller Architecture](#) on page 12-6

For more information, refer to the SDRAM Controller Block diagram.

Write Data Buffer

The write data buffer receives write data from the MPFE and passes the data to the PHY, on approval of the write request.

Related Information

[Memory Controller Architecture](#) on page 12-6

For more information, refer to the SDRAM Controller Block diagram.

ECC Block

The ECC block consists of an encoder and a decoder-corrector, which can detect and correct single-bit errors, and detect double-bit errors. The ECC block can correct single-bit errors and detect double-bit errors resulting from noise or other impairments during data transmission.

Note: The level of ECC support is package dependent.

Functional Description of the SDRAM Controller Subsystem

MPFE Operation Ordering

Operation ordering is defined and enforced within a port, but not between ports. All transactions received on a single port for overlapping addresses execute in order. Requests arriving at different ports have no guaranteed order of service, except when a first transaction has completed before the second arrives.

Avalon-MM does not support write acknowledgement. When a port is configured to support Avalon-MM, you should read from the location that was previously written to ensure that the write operation has completed. When a port is configured to support AXI, the master accessing the port can safely issue a read operation to the same address as a write operation as soon as the write has been acknowledged. To keep write latency low, writes are acknowledged as soon as the transaction order is guaranteed—meaning that any operations received on any port to the same address as the write operation are executed after the write operation.

To reduce read latency, the single-port logic can return read data out of order to the multi-port logic. The returned data is rearranged to its initial order on a per port basis by the multi-port logic and no traffic reordering occurs between individual ports.

Read Data Handling

The MPFE contains a read buffer shared by all ports. If a port is capable of receiving returned data then the read buffer is bypassed. If the size of a read transaction is smaller than twice the memory interface width, the buffer RAM cannot be bypassed. The lowest memory latency occurs when the port is ready to receive data and the full width of the interface is utilized.

MPFE Multi-Port Arbitration

The HPS SDRAM controller multi-port front end (MPFE) contains a programmable arbiter. The arbiter decides which MPFE port gains access to the single-port memory controller.

The SDRAM transaction size that is arbitrated is a burst of two beats. This burst size ensures that the arbiter does not favor one port over another when the incoming transaction size is a large burst.

The arbiter makes decisions based on two criteria: priority and weight. The priority is an absolute arbitration priority where the higher priority ports always win arbitration over the lower priority ports. Because multiple ports can be set to the same priority, the weight value refines the port choice by implementing a round-robin arbitration among ports set to the same priority. This programmable weight allows you to assign a higher arbitration value to a port in comparison to others such that the highest weighted port receives more transaction bandwidth than the lower weighted ports of the same priority.

Before arbitration is performed, the MPFE buffers are checked for any incoming transactions. The priority of each port that has buffered transactions is compared and the highest priority wins. If multiple ports are of the same highest priority value, the port weight is applied to determine which port wins. Because the arbiter only allows SDRAM-sized bursts into the single-port memory controller, large transactions may

need to be serviced multiple times before the read or write command is fully accepted to the single-port memory controller. The MPFE supports dynamic tuning of the priority and weight settings for each port, with changes committed into the SDRAM controller at fixed intervals of time.

Arbitration settings are applied to each port of the MPFE. The memory controller supports a mix of Avalon-MM and AXI protocols. As defined in the "Port Mappings" section, the Avalon-MM ports consume a single command port while the AXI ports consume a pair of command ports to support simultaneous read and write transactions. In total, there are ten command ports for the MPFE to arbitrate. The following table illustrates the command port mapping within the HPS as well as the ports exposed to the FPGA fabric.

Table 12-4: HPS SDRAM MPFE Command Port Mapping

Command Port	Allowed Functions	Data Size
0, 2, 4	FPGA fabric AXI read command ports FPGA fabric Avalon-MM read or write command ports	32-bit to 256-bit data
1, 3, 5	FPGA fabric AXI write command ports FPGA fabric Avalon-MM read or write command ports	
6	L3 AXI read command port	32-bit data
7	MPU AXI read command port	64-bit data
8	L3 AXI write command port	32-bit data
9	MPU AXI write command port	64-bit data

When the FPGA ports are configured for AXI, the command ports are always assigned in groups of two starting with even number ports 0, 2, or 4 assigned to the read command channel. For example, if you configure the first FPGA-to-SDRAM port as AXI and the second port as Avalon-MM, you can expect the following mapping:

- Command port 0 = AXI read
- Command port 1 = AXI write
- Command port 2 = Avalon-MM read and write

Setting the MPFE Priority

The priority of each of the ten command ports is configured through the `userpriority` field of the `mppriority` register. This 30-bit register uses 3 bits per port to configure the priority. The lowest priority is 0x0 and the highest priority is 0x7. The bits are mapped in ascending order with bits [2:0] assigned to command port 0 and bits [29:27] assigned to command port 9.

Setting the MPFE Static Weights

The static weight settings used in the round-robin command port priority scheme are programmed in a 128-bit field distributed among four 32-bit registers:

- mpweight_0_4
- mpweight_1_4
- mpweight_2_4
- mpweight_3_4

Each port is assigned a 5-bit value within the 128-bit field, such that port 0 is assigned to bits [4:0] of the mpweight_0_4 register, port 1 is assigned to bits [9:5] of the mpweight_0_4 register up to port 9, which is assigned to bits [49:45] contained in the mpweight_1_4 register. The valid weight range for each port is 0x0 to 0x1F, with larger static weights representing a larger arbitration share.

Bits[113:50] in the mpweight_1_4, mpweight_2_4 and mpweight_3_4 registers, hold the sum of weights for each priority. This 64-bit field is divided into eight fields of 8-bits, each representing the sum of static weights. Bits[113:50] are mapped in ascending order with bits [57:50] holding the sum of static weights for all ports with priority setting 0x0, and bits [113:106] holding the sum of static weights for all ports with priority setting 0x7.

Example Using MPFE Priority and Weights

In this example, the following settings apply:

- FPGA MPFE ports 0 is assigned to AXI read commands and port 1 is assigned to AXI write commands.
- FPGA MPFE port 2 is assigned to Avalon-MM read and write commands.
- L3 master ports (ports 6 and 8) and the MPU ports (port 7 and 9) are given the lowest priority but the MPU ports are configured with more arbitration static weight than the L3 master ports.
- The FPGA MPFE command ports are given the highest priority; however, AXI ports 0 and 1 are given a larger static weight because they carry the highest priority traffic in the entire system. Assigning a high priority and larger static weight ensures ports 0 and 1 will receive the highest quality-of-service (QoS).

The table below details the port weights and sum of weights.

Table 12-5: SDRAM MPFE Port Priority, Weights and Sum of Weights

Priority	Weights										Sum of Weights	
	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5	Port 6	Port 7	Port 8	Port 9		
-												-
1	10	10	5	0	0	0	0	0	0	0	0	25
0	0	0	0	0	0	0	1	4	1	4	4	10

If the FPGA-to-SDRAM ports are configured according to the table and if both ports are accessed concurrently, you can expect the AXI port to receive 80% of the total service. This value is determined by taking the sum of port 0 and 1 weights divided by the total weight for all ports of priority 1. The remaining 20% of bandwidth is allocated to the Avalon-MM port. With these port settings, any FPGA transaction buffered by the MPFE for either slave port blocks the MPU and L3 masters from having their buffered

transactions serviced. To avoid transaction starvation, you should assign ports the same priority level and adjust the bandwidth allocated to each port by adjusting the static weights.

MPFE Weight Calculation

The MPFE applies a deficit round-robin arbitration scheme to determine which port is serviced. The larger the port weight, the more often it is serviced. Ports are serviced only when they have buffered transactions and are set to the highest priority of all the ports that also have buffered transactions. The arbiter determines which port to service by examining the running weight of all the same ports at the same priority level and the largest running weight is serviced.

Each time a port is drained of all transactions, its running weight is set to 0x80. Each time a port is serviced, the static weight is added and the sum of weights is subtracted from the running weight for that port. Each time a port is not serviced (same priority as another port but has a lower running weight), the static weight for the port is added to the running weight of the port for that particular priority level. The running weight additions and subtractions are only applied to one priority level, so any time ports of a different priority level are being serviced, the running weight of a lower priority port is not modified.

MPFE Multi-Port Arbitration Considerations for Use

When using MPFE multi-port arbitration, the following considerations apply:

- To ensure that the dynamic weight value does not roll over when a port is serviced, the following equation should always be true:

$$(\text{sum of weights} - \text{static weight}) < 128$$

If the running weight remains less than 128, arbitration for that port remains functional.

- The memory controller commits the priority and weight registers into the MPFE arbiter once every 10 SDRAM clock cycles. As a result, when the `mppriority` register and `mpweight_*_4` registers are configured at run time, the update interval can occur while the registers are still being written and ports can have different priority or weights than intended for a brief period. Because the `mppriority` and `mpweight_*_4` registers can be updated in a single 32-bit transaction, Intel recommends updating first to ensure that transactions that need to be serviced have the appropriate priority after the next update. Because the static weights are divided among four 32-bit registers
- In addition to the `mppriority` register and `mpweight_*_*` registers, the `remappriority` register adds another level of priority to the port scheduling. By programming bit N in the `priorityremap` field of the `remappriority` register, any port with an absolute priority N is sent to the front of the single port command queue and is serviced before any other transaction. Please refer to the `remappriority` register for more details.

The scheduler is work-conserving. Write operations can only be scheduled when enough data for the SDRAM burst has been received. Read operations can only be scheduled when sufficient internal memory is free and the port is not occupying too much of the read buffer.

Related Information

[Port Mappings](#) on page 12-26

Refer to the "Port Mappings" section, for more information about command, read and write port assignments.

MPFE SDRAM Burst Scheduling

SDRAM burst scheduling recognizes addresses that access the same row/bank combination, known as open page accesses. Operations to a page are served in the order in which they are received by the single-port controller. Selection of SDRAM operations is a two-stage process. First, each pending transaction

must wait for its timers to be eligible for execution. Next, the transaction arbitrates against other transactions that are also eligible for execution.

The following rules govern transaction arbitration:

- High-priority operations take precedence over lower-priority operations
- If multiple operations are in arbitration, read operations have precedence over write operations
- If multiple operations still exist, the oldest is served first

A high-priority transaction in the SDRAM burst scheduler wins arbitration for that bank immediately if the bank is idle and the high-priority transaction's chip select, row, or column fields of the address do not match an address already in the single-port controller. If the bank is not idle, other operations to that bank yield until the high-priority operation is finished. If the chip select, row, and column fields match an earlier transaction, the high-priority transaction yields until the earlier transaction is completed.

Clocking

The FPGA fabric ports of the MPFE can be clocked at different frequencies. Synchronization is maintained by clock-domain crossing logic in the MPFE. Command ports can operate on different clock domains, but the data ports associated with a given command port must be attached to the same clock as that command port.

Note: A command port paired with a read and write port to form an Avalon-MM interface must operate at the same clock frequency as the data ports associated with it.

Single-Port Controller Operation

The single-port controller increases the performance of memory transactions through command and data re-ordering, enforcing bank policies, combining write operations and allowing burst transfers. Correction of single-bit errors and detection of double-bit errors is handled in the ECC module of the single-port Controller.

SDRAM Interface

The SDRAM interface is up to 40 bits wide and can accommodate 8-bit, 16-bit, 16-bit plus ECC, 32-bit, or 32-bit plus ECC configurations, depending on the device package. The SDRAM interface supports LPDDR2, DDR2, and DDR3 memory protocols.

Command and Data Reordering

The heart of the SDRAM controller is a command and data reordering engine. Command reordering allows banks for future transactions to be opened before the current transaction finishes.

Data reordering allows transactions to be serviced in a different order than they were received when that new order allows for improved utilization of the SDRAM bandwidth. Operations to the same bank and row are performed in order to ensure that operations which impact the same address preserve the data integrity.

The following figure shows the relative timing for a write/read/write/read command sequence performed in order and then the same command sequence performed with data reordering. Data reordering allows the write and read operations to occur in bursts, without bus turnaround timing delay or bank reassignment.

Figure 12-3: Data Reordering Effect

The SDRAM controller schedules among all pending row and column commands every clock cycle.

Bank Policy

The bank policy of the SDRAM controller allows users to request that a transaction's bank remain open after an operation has finished so that future accesses do not delay in activating the same bank and row combination. The controller supports only eight simultaneously-opened banks, so an open bank might get closed if the bank resource is needed for other operations.

Open bank resources are allocated dynamically as SDRAM burst transactions are scheduled. Bank allocation is requested automatically by the controller when an incoming transaction spans multiple SDRAM bursts or by the extended command interface. When a bank must be reallocated, the least-recently-used open bank is used as the replacement.

If the controller determines that the next pending command will cause the bank request to not be honored, the bank might be held open or closed depending on the pending operation. A request to close a bank with a pending operation in the timer bank pool to the same row address causes the bank to remain open. A request to leave a bank open with a pending command to the same bank but a different row address causes a precharge operation to occur.

Write Combining

The SDRAM controller combines write operations from successive bursts on a port where the starting address of the second burst is one greater than the ending address of the first burst and the resulting burst length does not overflow the 11-bit burst-length counters.

Write combining does not occur if the previous bus command has finished execution before the new command has been received.

Burst Length Support

The controller supports burst lengths of 2, 4, 8, and 16. Data widths of 8, 16, and 32 bits are supported for non-ECC operation and data widths of 24 and 40 bits are supported for operations with ECC enabled. The following table shows the type of SDRAM for each burst length.

Table 12-6: SDRAM Burst Lengths

Burst Length	SDRAM
4	LPDDR2, DDR2
8	DDR2, DDR3, LPDDR2

Burst Length	SDRAM
16	LPDDR2

Width Matching

The SDRAM controller automatically performs data width conversion.

ECC

The single-port controller supports memory ECC calculated by the controller.

The controller ECC employs standard Hamming logic to detect and correct single-bit errors and detect double-bit errors. The controller ECC is available for 16-bit and 32-bit widths, each requiring an additional 8 bits of memory, resulting in an actual memory width of 24-bits and 40-bits, respectively.

Note: The level of ECC support is package dependent.

Functions the controller ECC provides are:

- Byte Writes
- ECC Write Backs
- Notification of ECC Errors

Byte Writes

The memory controller performs a read-modify-write operation to ensure that the ECC data remains valid when a subset of the bits of a word is being written.

Byte writes with ECC enabled are executed as a read-modify-write. Typical operations only use a single entry in the timer bank pool. Controller ECC enabled sub-word writes use two entries. The first operation is a read and the second operation is a write. These two operations are transferred to the timer bank pool with an address dependency so that the write cannot be performed until the read data has returned. This approach ensures that any subsequent operations to the same address (from the same port) are executed after the write operation, because they are ordered on the row list after the write operation.

If an entire word is being written (but less than a full burst) and the DM pins are connected, no read is necessary and only that word is updated. If controller ECC is disabled, byte-writes have no performance impact.

ECC Write Backs

If the controller ECC is enabled and a read operation results in a correctable ECC error, the controller corrects the location in memory, if write backs are enabled. The correction results in scheduling a new read-modify-write.

A new read is performed at the location to ensure that a write operation modifying the location is not overwritten. The actual ECC correction operation is performed as a read-modify-write operation. ECC write backs are enabled and disabled through the `cfg_enable_ecc_code_overwrites` field in the `ctrlcfg` register.

Note: Double-bit errors do not generate read-modify-write commands. Instead, double-bit error address and count are reported through the `erraddr` and `dbecount` registers, respectively. In addition, a double-bit error interrupt can be enabled through the `dramintr` register.

User Notification of ECC Errors

When an ECC error occurs, an interrupt signal notifies the MPU subsystem, and the ECC error information is stored in the status registers. The memory controller provides interrupts for single-bit and double-bit errors.

The status of interrupts and errors are recorded in status registers, as follows:

- The `dramsts` register records interrupt status.
- The `dramintr` register records interrupt masks.
- The `sbecount` register records the single-bit error count.
- The `dbecount` register records the double-bit error count.
- The `erraddr` register records the address of the most recent error.

For a 32-bit interface, ECC is calculated across a span of 8 bytes, meaning the error address is a multiple of 8 bytes (4-bytes*2 burst length). To find the byte address of the word that contains the error, you must multiply the value in the `erraddr` register by 8.

Related Information

[Cortex-A9 Microprocessor Unit Subsystem](#) on page 10-1
Information about ECC error interrupts

Interleaving Options

The controller supports the following address-interleaving options:

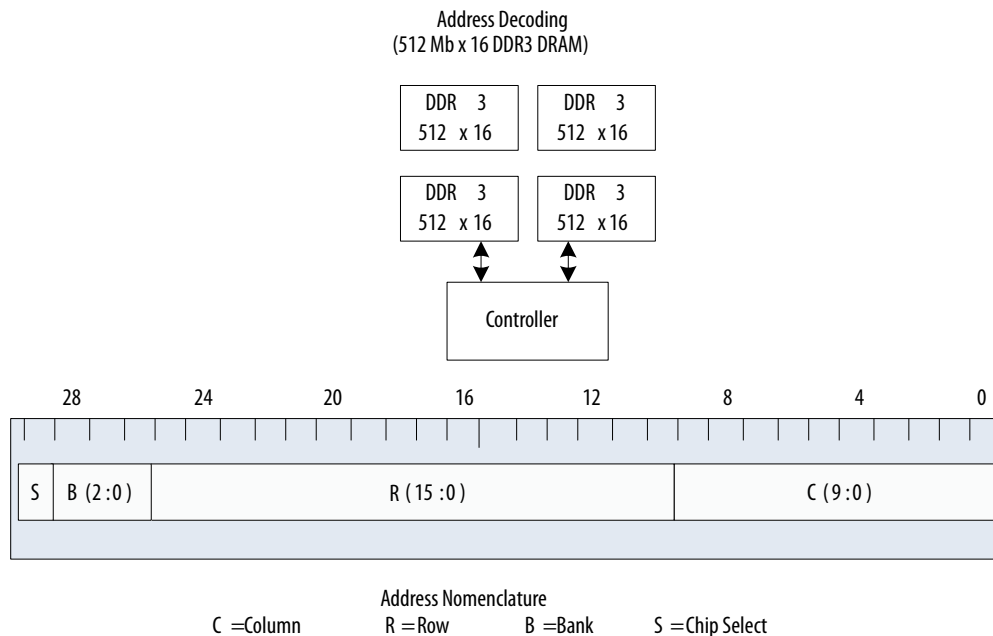

- Non-interleaved
- Bank interleave without chip select interleave
- Bank interleave with chip select interleave

The following interleaving examples use 512 megabits (Mb) x 16 DDR3 chips and are documented as byte addresses. For RAMs with smaller address fields, the order of the fields stays the same but the widths may change.

Non-interleaved

RAM mapping is non-interleaved.

Figure 12-4: Non-interleaved Address Decoding

Bank Interleave Without Chip Select Interleave

Bank interleave without chip select interleave swaps row and bank from the non-interleaved address mapping. This interleaving allows smaller data structures to spread across all banks in a chip.

Figure 12-5: Bank Interleave Without Chip Select Interleave Address Decoding

Bank Interleave with Chip Select Interleave

Bank interleave with chip select interleave moves the row address to the top, followed by chip select, then bank, and finally column address. This interleaving allows smaller data structures to spread across multiple banks and chips (giving access to 16 total banks for multithreaded access to blocks of memory). Memory timing is degraded when switching between chips.

Figure 12-6: Bank Interleave With Chip Select Interleave Address Decoding

AXI-Exclusive Support

The single-port controller supports AXI-exclusive operations. The controller implements a table shared across all masters, which can store up to 16 pending writes. Table entries are allocated on an exclusive read and table entries are deallocated on a successful write to the same address by any master.

Any exclusive write operation that is not present in the table returns an exclusive fail as acknowledgement to the operation. If the table is full when the exclusive read is performed, the table replaces a random entry.

Note: When using AXI-exclusive operations, accessing the same location from Avalon-MM interfaces can result in unpredictable results.

Memory Protection

The single-port controller has address protection to allow the software to configure basic protection of memory from all masters in the system. If the system has been designed exclusively with AMBA masters, TrustZone® is supported. Ports that use Avalon-MM can be configured for port level protection.

Memory protection is based on physical addresses in memory. The single-port controller can configure up to 20 rules to allow or prevent masters from accessing a range of memory based on their AxIDs, level of security and the memory region being accessed. If no rules are matched in an access, then default settings take effect.

The rules are stored in an internal protection table and can be accessed through indirect addressing offsets in the `protruledwr` register in the CSR. To read a specific rule, set the `readrule` bit and write the appropriate offset in the `ruleoffset` field of the `protruledwr` register.

To write a new rule, three registers in the CSR must be configured:

1. The `protportdefault` register is programmed to control the default behavior of memory accesses when no rules match. When a bit is clear, all default accesses from that port pass. When a bit is set, all default accesses from that port fails. The bits are assigned as follows:

Table 12-7: `protportdefault` register

Bits	Description
31:10	reserved
9	When this bit is set to 1, deny CPU writes during a default transaction. When this bit is clear, allow CPU writes during a default transaction.
8	When this bit is set to 1, deny L3 writes during a default transaction. When this bit is clear, allow L3 writes during a default transaction.
7	When this bit is set to 1, deny CPU reads during a default transaction. When this bit is clear, allow CPU reads during a default transaction.
6	When this bit is set to 1, deny L3 reads during a default transaction. When this bit is clear, allow L3 reads during a default transaction.

Bits	Description
5:0	<p>When this bit is set to 1, deny accesses from FPGA-to-SDRAM ports 0 through 5 during a default transaction.</p> <p>When this bit is clear, allow accesses from FPGA-to-SDRAM ports 0 through 5 during a default transaction.</p>

- The `protruleid` register gives the bounds of the AxID value that allows an access
- The `protruledata` register configures the specific security characteristics for a rule.

Once the registers are configured, they can be committed to the internal protection table by programming the `ruleoffset` field and setting the `writerule` bit in the `protruledwr` register.

Secure and non-secure regions are specified by rules containing a starting address and ending address with 1 MB boundaries for both addresses. You can override the port defaults and allow or disallow all transactions.

The following table lists the fields that you can specify for each rule.

Table 12-8: Fields for Rules in Memory Protection Table

Field	Width	Description
Valid	1	Set to 1 to activate the rule. Set to 0 to deactivate the rule.
Port Mask ⁽²⁹⁾	10	Specifies the set of ports to which the rule applies, with one bit representing each port, as follows: bits 0 to 5 correspond to FPGA fabric ports 0 to 5, bit 6 corresponds to AXI L3 interconnect read, bit 7 is the CPU read, bit 8 is L3 interconnect write, and bit 9 is the CPU write.
AxID_low ⁽²⁹⁾	12	Low transfer AxID of the rules to which this rule applies. Incoming transactions match if they are greater than or equal to this value. Ports with smaller AxIDs have the AxID shifted to the lower bits and zero padded at the top.
AxID_high ⁽²⁹⁾	12	High transfer AxID of the rules to which this rule applies. Incoming transactions match if they are less than or equal to this value.
Address_low	12	Points to a 1MB block and is the lower address. Incoming addresses match if they are greater than or equal to this value.
Address_high	12	Upper limit of address. Incoming addresses match if they are less than or equal to this value.

⁽²⁹⁾ Although AxID and Port Mask could be redundant, including both in the table allows possible compression of rules. If masters connected to a port do not have contiguous AxIDs, a port-based rule might be more efficient than an AxID-based rule, in terms of the number of rules needed.

Field	Width	Description
Protection	2	A value of 0x0 indicates that the rule applies to secure transactions; a value of 0x1 indicates the rule applies to non-secure transactions. Values 0x2 and 0x3 set the region to shared, meaning both secure and non-secure accesses are valid.
Fail/allow	1	Set this value to 1 to force the operation to fail or succeed.

Each port has a default access status of either allow or fail. Rules with the opposite allow/fail value can override the default. The system evaluates each transaction against every rule in the memory protection table. If a transaction arrives at a port that defaults to access allowed, it fails only if a rule with the fail bit matches the transaction. Conversely, if a transaction arrives at a port that has the default rule set to access denied, it allows access only if there is a matching rule that forces access allowed. Transactions that fail the protection rules return a slave error (SLVERR).

The recommended sequence for writing a rule is:

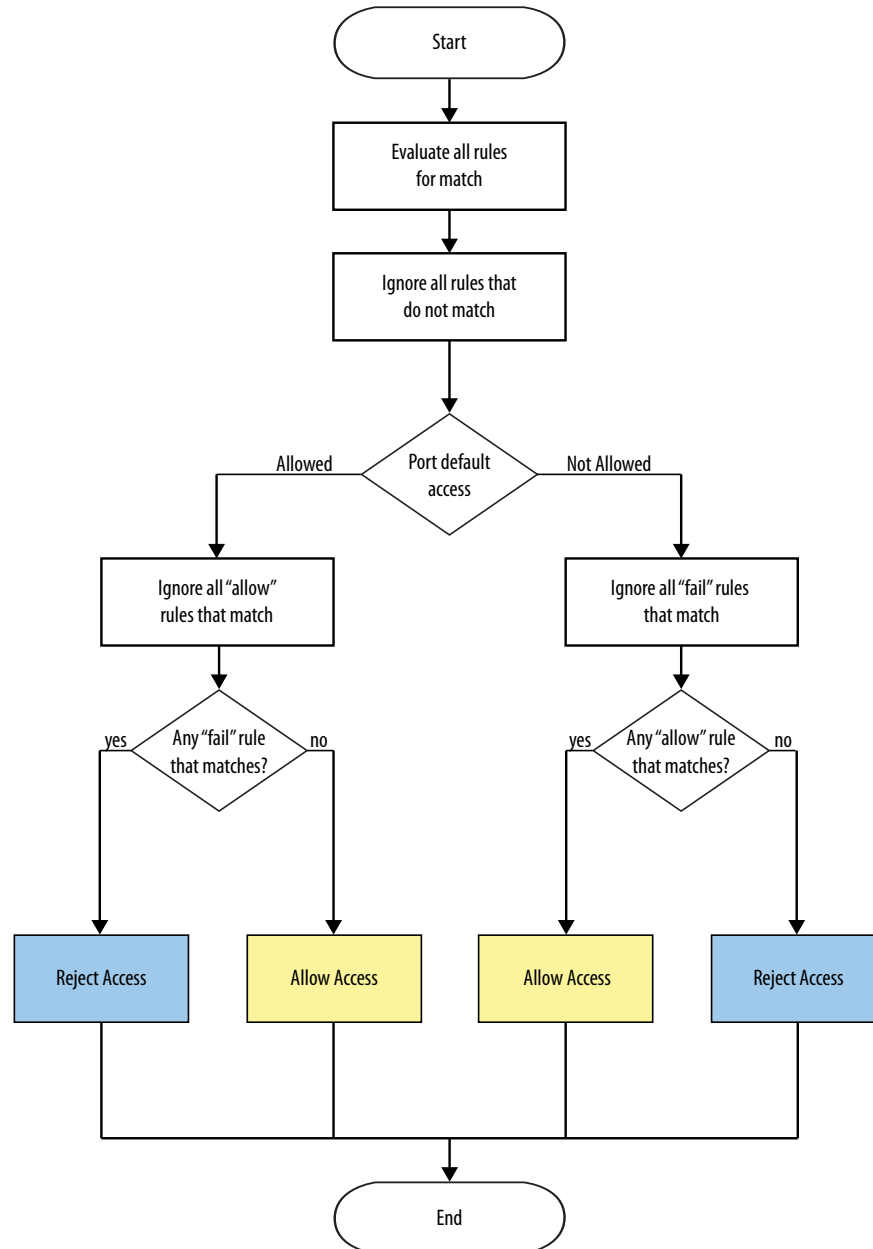

1. Write the `protruledwr` register fields as follows:
 - `ruleoffset` = offset selected by user that points to indirect offset in an internal protection table.
 - `writerule` = 0
 - `readrule` = 0
2. Write the `protruleaddr`, `protruleid`, and `protruledata` registers so you configure the rule you would like to enforce.
3. Write the `protruledwr` register fields as follows:
 - `ruleoffset` = offset of the rule that needs to be written
 - `writerule` = 1
 - `readrule` = 0

Similarly, the recommended sequence for reading a rule is:

1. Write the `protruledwr` register fields as follows:
 - `ruleoffset` = offset of the rule that needs to be written
 - `writerule` = 0
 - `readrule` = 0
2. Write the `protruledwr` register fields as follows:
 - `ruleoffset` = offset of the rule that needs to be read
 - `writerule` = 0
 - `readrule` = 1
3. Read the values of the `protruleaddr`, `protruleid`, and `protruledata` registers to determine the rule parameters.

The following figure represents an overview of how the protection rules are applied. There is no priority among the 20 rules. All rules are always evaluated in parallel.

Figure 12-7: SDRAM Protection Access Flow Diagram

Exclusive transactions are security checked on the read operation only. A write operation can occur only if a valid read is marked in the internal exclusive table. Consequently, a master performing an exclusive read followed by a write, can write to memory only if the exclusive read was successful.

Related Information

Arm TrustZone®

For more information about TrustZone® refer to the Arm web page.

Example of Configuration for TrustZone

For a TrustZone configuration, memory is TrustZone divided into a range of memory accessible by secure masters and a range of memory accessible by non-secure masters. The two memory address ranges may have a range of memory that overlaps.

This example implements the following memory configuration:

- 2 GB total RAM size
- 0—512 MB dedicated secure area
- 513—576 MB shared area
- 577—2048 MB dedicated non-secure area

Figure 12-8: Example Memory Configuration

In this example, each port is configured by default to disallow all accesses. The following table shows the two rules programmed into the memory protection table.

Table 12-9: Rules in Memory Protection Table for Example Configuration

Rule #	Port Mask	AxID Low	AxID High	Address Low	Address High	protruledata.security	Fail/Allow
1	0x3FF (1023)	0x000	0xFFFF (4095)	0	576	0x1	Allow
2	0x3FF (1023)	0x000	0xFFFF (4095)	512	2047	0x0	Allow

The port mask value, AxID Low, and AxID High, apply to all ports and all transfers within those ports. Each access request is evaluated against the memory protection table, and will fail unless there is a rule match allowing a transaction to complete successfully.

Table 12-10: Result for a Sample Set of Transactions

Operation	Source	Address Accesses	Security Access Type	Result	Comments
Read	CPU	4096	secure	Allow	Matches rule 1.
Write	CPU	536, 870, 912	secure	Allow	Matches rule 1.
Write	L3 attached masters	605, 028, 350	secure	Fail	Does not match rule 1 (out of range of the address field), does not match rule 2 (protection bit incorrect).
Read	L3 attached masters	4096	non-secure	Fail	Does not match rule 1 (AxPROT signal value wrong), does not match rule 2 (not in address range).
Write	CPU	536, 870, 912	non-secure	Allow	Matches rule 2.
Write	L3 attached masters	605, 028, 350	non-secure	Allow	Matches rule 2.

Note: If a master is using the Accelerator Coherency Port (ACP) to maintain cache coherency with the Cortex-A9 MPCore processor, then the address ranges in the rules of the memory protection table should be made mutually exclusive, such that the secure and non-secure regions do not overlap and any area that is shared is part of the non-secure region. This configuration prevents coherency issues from occurring.

SDRAM Power Management

The SDRAM controller subsystem supports the following power saving features in the SDRAM:

- Partial array self-refresh (PASR)
- Power down
- Deep power down for LPDDR2

To enable self-refresh for the memories of one or both chip selects, program the `selfshreq` bit and the `sefrshmask` bit in the `lowpwreq` register.

Power-saving mode initiates either due to a user command or from inactivity. The number of idle clock cycles after which a memory can be put into power-down mode is programmed through the `autopdycycles` field of the `lowpwrtiming` register.

Power-down mode forces the SDRAM burst-scheduling bank-management logic to close all banks and issue the power down command. The SDRAM automatically reactivates when an active SDRAM command is received.

To enable deep power down request for the LPDDR2 memories of one or both chip selects, program the `deepwrnreq` bit and the `deepwrnmask` field of the `lowpwreq` register.

Other power-down modes are performed only under user control.

DDR PHY

The DDR PHY connects the memory controller and external memory devices in the speed critical command path.

The DDR PHY implements the following functions:

- Calibration—the DDR PHY supports the JEDEC-specified steps to synchronize the memory timing between the controller and the SDRAM chips. The calibration algorithm is implemented in software.
- Memory device initialization—the DDR PHY performs the mode register write operations to initialize the devices. The DDR PHY handles re-initialization after a deep power down.
- Single-data-rate to double-data-rate conversion.

DDR Calibration

The SDRAM Controller calibrates across multiple SDRAM banks. An entire row is calibrated at bank 0 and bank 7 in each rank. Thus, if you have a 4 Gb memory made up of two ranks, rank 0 is calibrated in banks 0 and 7, and rank 1 is calibrated in banks 0 and 7.

You can refer to the "Interleaving Options" section to identify which memory locations are affected by calibration.

Note: The SDRAM Controller does not preserve memory contents through a calibration cycle.

Related Information

[Interleaving Options](#) on page 12-17

Clocks

All clocks are assumed to be asynchronous with respect to the `ddr_dqs_clk` memory clock. All transactions are synchronized to memory clock domain.

Table 12-11: SDRAM Controller Subsystem Clock Domains

Clock Name	Description
<code>ddr_dq_clk</code>	Clock for PHY
<code>ddr_dqs_clk</code>	Clock for MPFE, single-port controller, CSR access, and PHY
<code>ddr_2x_dqs_clk</code>	Clock for PHY that provides up to 2 times <code>ddr_dq_clk</code> frequency
<code>l4_sp_clk</code>	Clock for CSR interface

Clock Name	Description
mpu_l2_ram_clk	Clock for MPU interface
l3_main_clk	Clock for L3 interface
f2h_sdram_clk[5:0]	Six separate clocks used for the FPGA-to-HPS SDRAM ports to the FPGA fabric

In terms of clock relationships, the FPGA fabric connects the appropriate clocks to write data, read data, and command ports for the constructed ports.

Related Information

[Clock Manager](#) on page 3-1

Resets

The SDRAM controller subsystem supports a full reset (cold reset) and a warm reset. The SDRAM controller can be configured to preserve memory contents during a warm reset.

To preserve memory contents, the reset manager can request that the single-port controller place the SDRAM in self-refresh mode prior to issuing the warm reset. If self-refresh mode is enabled before the warm reset to preserve memory contents, the PHY and the memory timing logic is not reset, but the rest of the controller is reset.

Related Information

[Reset Manager](#) on page 4-1

Taking the SDRAM Controller Subsystem Out of Reset

When a cold or warm reset is issued in the HPS, the Reset Manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the Reset Manager's corresponding reset trigger.

Related Information

[Modules Requiring Software Deassert](#) on page 4-9

For more details about reset registers, refer to the Reset Manager.

Port Mappings

The memory interface controller has a set of command, read data, and write data ports that support AXI3, AXI4 and Avalon-MM. Tables are provided to identify port assignments and functions.

Table 12-12: Command Port Assignments

Command Port	Allowed Functions
0, 2, 4	FPGA fabric AXI read command ports FPGA fabric Avalon-MM read or write command ports
1, 3, 5	FPGA fabric AXI write command ports FPGA fabric Avalon-MM read or write command ports
6	L3 AXI read command port
7	MPU AXI read command port
8	L3 AXI write command port
9	MPU AXI write command port

Table 12-13: Read Port Assignments

Read Port	Allowed Functions
0, 1, 2, 3	64-bit read data from the FPGA fabric. When 128-bit data read ports are created, then read data ports 0 and 1 get paired as well as 2 and 3.
4	32-bit L3 read data port
5	64-bit MPU read data port

Table 12-14: Write Port Assignments

Write Port	Allowed Functions
0, 1, 2, 3	64-bit write data from the FPGA fabric. When 128-bit data write ports are created, then write data ports 0 and 1 get paired as well as 2 and 3.
4	32-bit L3 write data port
5	64-bit MPU write data port

Initialization

The SDRAM controller subsystem has control and status registers (CSRs) which control the operation of the controller including DRAM type, DRAM timing parameters and relative port priorities. It also has a small set of bits which depend on the FPGA fabric to configure ports between the memory controller and

the FPGA fabric; these bits are set for you when you configure your implementation using the HPS GUI in Platform Designer (Standard).

The CSRs are configured using a dedicated slave interface, which provides access to the registers. This region controls all SDRAM operation, MPFE scheduler configuration, and PHY calibration.

The FPGA fabric interface configuration is programmed into the FPGA fabric and the values of these register bits can be read by software. The ports can be configured without software developers needing to know how the FPGA-to-HPS SDRAM interface has been configured.

FPGA-to-SDRAM Protocol Details

The following topics summarize signals for the Avalon-MM Bidirectional port, Avalon-MM Write Port, Avalon-MM Read Port, and AXI port.

Note: If your device has multiple FPGA hardware images, then the same FPGA-to-SDRAM port configuration should be used across all designs.

Avalon-MM Bidirectional Port

The Avalon-MM bidirectional ports are standard Avalon-MM ports used to dispatch read and write operations.

Each configured Avalon-MM bidirectional port consists of the signals listed in the following table.

Table 12-15: Avalon-MM Bidirectional Port Signals

Name	Bit Width	Input/Output Direction	Function
clk	1	In	Clock for the Avalon-MM interface
read	1	In	Indicates read transaction ⁽³⁰⁾
write	1	In	Indicates write transaction ⁽³⁰⁾
address	32	In	Address of the transaction
readdata	32, 64, 128, or 256	Out	Read data return
readdatavalid	1	Out	Indicates the readdata signal contains valid data in response to a previous read request.
writedata	32, 64, 128, or 256	In	Write data for a transaction
byteenable	4, 8, 16, 32	In	Byte enables for each write byte lane

⁽³⁰⁾ The Avalon-MM protocol does not allow read and write transactions to be posted concurrently.

Name	Bit Width	Input/Output Direction	Function
waitrequest	1	Out	Indicates need for additional cycles to complete a transaction
burstcount	11	In	Transaction burst length. The value of the maximum <code>burstcount</code> parameter must be a power of 2.

The read and write interfaces are configured to the same size. The byte-enable size scales with the data bus size.

Related Information

[Avalon Interface Specifications](#)

Information about the Avalon-MM protocol

Avalon-MM Write-Only Port

The Avalon-MM write-only ports are standard Avalon-MM ports used to dispatch write operations. Each configured Avalon-MM write port consists of the signals listed in the following table.

Table 12-16: Avalon-MM Write-Only Port Signals

Name	Bits	Direction	Function
reset	1	In	Reset
clk	1	In	Clock
write	1	In	Indicates write transaction
address	32	In	Address of the transaction
writedata	32, 64, 128, or 256	In	Write data for a transaction
byteenable	4, 8, 16, 32	In	Byte enables for each write byte
waitrequest	1	Out	Indicates need for additional cycles to complete a transaction
burstcount	11	In	Transaction burst length

Related Information[Avalon Interface Specifications](#)

Information about the Avalon-MM protocol

Avalon-MM Read Port

The Avalon-MM read ports are standard Avalon-MM ports used only to dispatch read operations. Each configured Avalon-MM read port consists of the signals listed in the following table.

Table 12-17: Avalon-MM Read Port Signals

Name	Bits	Direction	Function
reset	1	In	Reset
clk	1	In	Clock
read	1	In	Indicates read transaction
address	32	In	Address of the transaction
readdata	32, 64, 128, or 256	Out	Read data return
readdatavalid	1	Out	Flags valid cycles for read data return
waitrequest	1	Out	Indicates the need for additional cycles to complete a transaction. Needed for read operations when delay is needed to accept the read command.
burstcount	11	In	Transaction burst length

Related Information[Avalon Interface Specifications](#)

Information about the Avalon-MM protocol

AXI Port

The AXI port uses an AXI-3 interface. Each configured AXI port consists of the signals listed in the following table. Because the AXI protocol allows simultaneous read and write commands to be issued, two SDRAM control ports are required to form an AXI interface.

Table 12-18: AXI Port Signals

Name	Bits	Direction	Channel	Function
ARESETn	1	In	n/a	Reset

Name	Bits	Direction	Channel	Function
ACLK	1	In	n/a	Clock
AWID	4	In	Write address	Write identification tag
AWADDR	32	In	Write address	Write address
AWLEN	4	In	Write address	Write burst length
AWSIZE	3	In	Write address	Width of the transfer size
AWBURST	2	In	Write address	Burst type
AWLOCK	2	In	Write address	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)
AWCACHE	4	In	Write address	Cache policy type
AWPROT	3	In	Write address	Protection-type signal used to indicate whether a transaction is secure or non-secure
AWREADY	1	Out	Write address	Indicates ready for a write command
AWVALID	1	In	Write address	Indicates valid write command.
WID	4	In	Write data	Write data transfer ID
WDATA	32, 64, 128 or 256	In	Write data	Write data
WSTRB	4, 8, 16, 32	In	Write data	Byte-based write data strobe. Each bit width corresponds to 8 bit wide transfer for 32-bit wide to 256-bit wide transfer.
WLAST	1	In	Write data	Last transfer in a burst
WVALID	1	In	Write data	Indicates write data and strobes are valid
WREADY	1	Out	Write data	Indicates ready for write data and strobes
BID	4	Out	Write response	Write response transfer ID
BRESP	2	Out	Write response	Write response status
BVALID	1	Out	Write response	Write response valid signal
BREADY	1	In	Write response	Write response ready signal
ARID	4	In	Read address	Read identification tag
ARADDR	32	In	Read address	Read address
ARLEN	4	In	Read address	Read burst length
ARSIZE	3	In	Read address	Width of the transfer size
ARBURST	2	In	Read address	Burst type
ARLOCK	2	In	Read address	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)

Name	Bits	Direction	Channel	Function
ARCACHE	4	In	Read address	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)
ARPROT	3	In	Read address	Protection-type signal used to indicate whether a transaction is secure or non-secure
ARREADY	1	Out	Read address	Indicates ready for a read command
ARVALID	1	In	Read address	Indicates valid read command
RID	4	Out	Read data	Read data transfer ID
RDATA	32, 64, 128 or 256	Out	Read data	Read data
RRESP	2	Out	Read data	Read response status
RLAST	1	Out	Read data	Last transfer in a burst
RVALID	1	Out	Read data	Indicates read data is valid
RREADY	1	In	Read data	Read data channel ready signal

AMBA Open Specifications, including information about the AXI-3 interface

SDRAM Controller Subsystem Programming Model

SDRAM controller configuration occurs through software programming of the configuration registers using the CSR interface.

HPS Memory Interface Architecture

The configuration and initialization of the memory interface by the Arm processor is a significant difference compared to the FPGA memory interfaces, and results in several key differences in the way the HPS memory interface is defined and configured.

Boot-up configuration of the HPS memory interface is handled by the initial software boot code, not by the FPGA programmer, as is the case for the FPGA memory interfaces. The Intel Quartus® Prime software is involved in defining the configuration of I/O ports which is used by the boot-up code, as well as timing analysis of the memory interface. Therefore, the memory interface must be configured with the correct PHY-level timing information. Although configuration of the memory interface in Platform Designer (Standard) is still necessary, it is limited to PHY- and board-level settings.

HPS Memory Interface Configuration

To configure the external memory interface components of the HPS, open the HPS interface by selecting the Arria V/Cyclone V Hard Processor System component in Platform Designer (Standard). Within the HPS interface, select the EMIF tab to open the EMIF parameter editor.

The EMIF parameter editor contains four additional tabs: PHY Settings, Memory Parameters, Memory Timing, and Board Settings. The parameters available on these tabs are similar to those available in the parameter editors for non-SoC device families.

There are significant differences between the EMIF parameter editor for the Hard Processor System and the parameter editors for non-SoC devices, as follows:

- Because the HPS memory controller is not configurable through the Intel Quartus Prime software, the Controller and Diagnostic tabs, which exist for non-SoC devices, are not present in the EMIF parameter editor for the hard processor system.
- Unlike the protocol-specific parameter editors for non-SoC devices, the EMIF parameter editor for the Hard Processor System supports multiple protocols, therefore there is an SDRAM Protocol parameter, where you can specify your external memory interface protocol. By default, the EMIF parameter editor assumes the DDR3 protocol, and other parameters are automatically populated with DDR3-appropriate values. If you select a protocol other than DDR3, change other associated parameter values appropriately.
- Unlike the memory interface clocks in the FPGA, the memory interface clocks for the HPS are initialized by the boot-up code using values provided by the configuration process. You may accept the values provided by UniPHY, or you may use your own PLL settings. If you choose to specify your own PLL settings, you must indicate that the clock frequency that UniPHY should use is the requested clock frequency, and not the achieved clock frequency calculated by UniPHY.

Note: The HPS does not support EMIF synthesis generation, compilation, or timing analysis. The HPS hard memory controller cannot be bonded with another hard memory controller on the FPGA portion of the device.

HPS Memory Interface Simulation

Platform Designer (Standard) provides a complete simulation model of the HPS memory interface controller and PHY, providing cycle-level accuracy, comparable to the simulation models for the FPGA memory interface.

The simulation model supports only the skip-cal simulation mode; quick-cal and full-cal are not supported. An example design is not provided. However, you can create a test design by adding the traffic generator component to your design using Platform Designer (Standard). Also, the HPS simulation model does not use external memory pins to connect to the DDR memory model; instead, the memory model is incorporated directly into the HPS SDRAM interface simulation modules. The memory instance incorporated into the HPS model is in the simulation model hierarchy at: `hps_0/fpga_interfaces/f2sdram/hps_sdram_inst/mem/`

Simulation of the FPGA-to-SDRAM interfaces requires that you first bring the interfaces out of reset, otherwise transactions cannot occur. Connect the H2F reset to the F2S port resets and add a stage to your testbench to assert and deassert the H2F reset in the HPS. Appropriate Verilog code is shown below:

```
initial
begin
    // Assert reset
    <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_assert();
    // Delay
    #1
    // Deassert reset
    <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_deassert();
end
```

Generating a Preloader Image for HPS with EMIF

To generate a preloader image for an HPS-based external memory interface, you must complete the following tasks:

- Create a project in Platform Designer (Standard).
- Create a top-level file and add constraints.
- Create a preloader BSP file.
- Create a preloader image.

Creating a Project in Platform Designer (Standard)

Before you can generate a preloader image, you must create a project in Platform Designer (Standard), as follows:

1. On the **Tools** menu in the Intel Quartus Prime software, click **Platform Designer (Standard)**.
2. Under **Component library**, expand **Embedded Processor System**, select **Hard Processor System** and click **Add**.
3. Specify parameters for the **FPGA Interfaces**, **Peripheral Pin Multiplexing**, and **HPS Clocks**, based on your design requirements.
4. On the **SDRAM** tab, select the SDRAM protocol for your interface.
5. Populate the necessary parameter fields on the **PHY Settings**, **Memory Parameters**, **Memory Timing**, and **Board Settings** tabs.
6. Add other components in your design and make the appropriate bus connections.
7. Save the project.
8. Click **Generate** on the **Generation** tab. Platform Designer (Standard) generates the design.

Creating a Top-Level File and Adding Constraints

This topic describes adding your Platform Designer (Standard) system to your top-level design and adding constraints to your design.

1. Add your Platform Designer (Standard) system to your top-level design.
2. Add the Intel Quartus Prime IP files (.qip) generated in step 2, to your Intel Quartus Prime project.
3. Perform analysis and synthesis on your design.
4. Constrain your EMIF design by running the `<variation_name>_p0_pin_assignments.tcl` pin constraints script.
5. Add other necessary constraints—such as timing constraints, location assignments, and pin I/O standard assignments—for your design.
6. Compile your design to generate an SRAM object file (.sof) and the hardware handoff files necessary for creating a preloader image.

Note: You must regenerate the hardware handoff files whenever the HPS configuration changes; for example, due to changes in Peripheral Pin Multiplexing or I/O standard for HPS pins.

Debugging HPS SDRAM in the Preloader

To assist in debugging your design, tools are available at the preloader stage.

- UART or semihosting printout
- Simple memory test
- Debug report
- Predefined data patterns

The following topics provide procedures for implementing each of the above tools.

Enabling UART or Semihosting Printout

UART printout is enabled by default. If UART is not available on your system, you can use semihosting together with the debugger tool. To enable semihosting in the Preloader, follow these steps:

1. When you create the `.bsp` file in the BSP Editor, select **SEMIHOSTING** in the `spl.debug` window.

2. Enable semihosting in the debugger, by typing `set semihosting enabled true` at the command line in the debugger.

```

Commands | History | Scripts | Linked: New_configuration (1)

set semihosting enabled true
Semihosting server socket created at port 8000

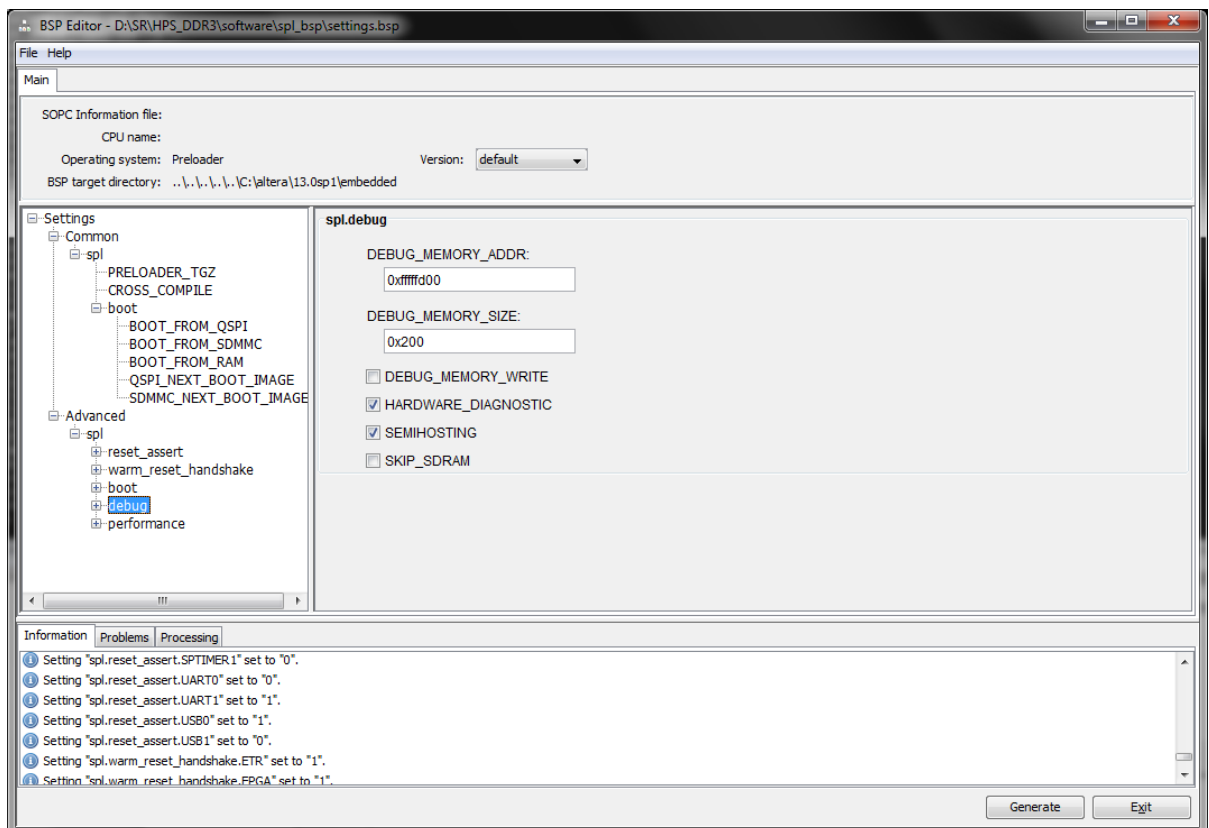

Command: set semihosting enabled true
Submit

```

Enabling Simple Memory Test

After the SDRAM is successfully calibrated, a simple memory test may be performed using the debugger.

1. When you create the .bsp file in the BSP Editor, select **HARDWARE_DIAGNOSTIC** in the **spl.debug** window..

2. The simple memory test assumes SDRAM with a memory size of 1 GB. If your board contains a different SDRAM memory size, open the file `<design folder>\spl_bsp\uboot-socfpga\`

include\configs\socfpga_cyclone5.h in a text editor, and change the `PHYS_SDRAM_1_SIZE` parameter at line 292 to specify your actual memory size in bytes.

```
socfpga_cyclone5.h
278  * Hardware drivers
279  */
280
281  /*
282  * SDRAM Memory Map
283  */
284  /* We have 1 bank of DRAM */
285  #define CONFIG_NR_DRAM_BANKS      1
286  /* SDRAM Bank #1 */
287  #define CONFIG_SYS_SDRAM_BASE    0x00000000
288  /* SDRAM memory size */
289  #ifdef CONFIG_SOCFPGA_VIRTUAL_TARGET
290  #define PHYS_SDRAM_1_SIZE        0x80000000
291  #else
292  #define PHYS_SDRAM_1_SIZE        0x40000000
293  #endif
294  /* SDRAM Bank #1 base address */
295  #define PHYS_SDRAM_1              CONFIG_SYS_SDRAM_BASE
296  /* memtest setup */
297  /* Begin and end addresses of the area used by the simple memory test.c */
298  #define CONFIG_SYS_MEMTEST_START 0x00000000
299  #define CONFIG_SYS_MEMTEST_END  PHYS_SDRAM_1_SIZE
300
```

Enabling the Debug Report

You can enable the SDRAM calibration sequencer to produce a debug report on the UART printout or semihosting output. To enable the debug report, follow these steps:

1. After you have enabled the UART or semihosting, open the file `<project directory>\hps_isw_handoff\sequencer_defines.hin` in a text editor.
2. Locate the line `#define RUNTIME_CAL_REPORT 0` and change it to `#define RUNTIME_CAL_REPORT 1`.

```

Analysis of Debug Report

The following analysis will help you interpret the debug report.

- The Read Deskew and Write Deskew results shown in the debug report are before calibration. (Before calibration results are actually from the window seen *during* calibration, and are most useful for debugging.)
- For each DQ group, the Write Deskew, Read Deskew, DM Deskew, and Read after Write results map to the before-calibration margins reported in the EMIF Debug Toolkit.

Note: The Write Deskew, Read Deskew, DM Deskew, and Read after Write results are reported in delay steps (nominally 25ps, in Arria V and Cyclone V devices), not in picoseconds.

- DQS Enable calibration is reported as a VFIFO setting (in one clock period steps), a phase tap (in one-eighth clock period steps), and a delay chain step (in 25ps steps).

```
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; Start VFIFO 5 ; Phase 6 ; Delay 4
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; End VFIFO 6 ; Phase 5 ; Delay 9
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; Center VFIFO 6 ; Phase 2 ; Delay 1
```

Analysis of DQS Enable results: A VFIFO tap is 1 clock period, a phase is 1/8 clock period (45 degrees) and delay is nominally 25ps per tap. The DQSen window is the difference between the start and end—for the above example, assuming a frequency of 400 MHz (2500ps), that calculates as follows: start is $5 * 2500 + 6 * 2500 / 8 + 4 * 25 = 14475\text{ps}$. By the same calculation, the end is 16788ps. Consequently, the DQSen window is 2313ps.

- The size of a read window or write window is equal to (left edge + right edge) * delay chain step size. Both the left edge and the right edge can be negative or positive.:

```
SEQ.C: Read Deskew ; DQ 0 ; Rank 0 ; Left edge 18 ; Right edge 27 ; DQ
delay 0 ; DQS delay 8
SEQ.C: Write Deskew ; DQ 0 ; Rank 0 ; Left edge 30 ; Right edge 17 ; DQ
delay 6 ; DQS delay 4
```

Analysis of DQ and DQS delay results: The DQ and DQS output delay (write) is the D5 delay chain. The DQ input delay (read) is the D1 delay chain, the DQS input delay (read) is the D4 delay chain.

- Consider the following example of latency results:

```
SEQ.C: LFIFO Calibration ; Latency 10
```

Analysis of latency results: This is the calibrated PHY read latency. The EMIF Debug Toolkit does not report this figure. This latency is reported in clock cycles.

- Consider the following example of FOM results:

```
SEQ.C: FOM IN = 83
SEQ.C: FOM OUT = 91
```

Analysis of FOM results: The FOM IN value is a measure of the health of the read interface; it is calculated as the sum over all groups of the minimum margin on DQ plus the margin on DQS, divided by 2. The FOM OUT is a measure of the health of the write interface; it is calculated as the sum over all groups of the minimum margin on DQ plus the margin on DQS, divided by 2. You may refer to these values as indicators of improvement when you are experimenting with various termination schemes, assuming there are no individual misbehaving DQ pins.

- The debug report does not provide delay chain step size values. The delay chain step size varies with device speed grade. Refer to your device data sheet for exact incremental delay values for delay chains.

Writing a Predefined Data Pattern to SDRAM in the Preloader

You can include your own code to write a predefined data pattern to the SDRAM in the preloader for debugging purposes.

1. Include your code in the file: `<project_folder>\software\spl_bsp\uboot-socfpga\arch\arm\cpu\armv7\socfpga\spl.c`.

Adding the following code to the `spl.c` file causes the controller to write walking 1s and walking 0s, repeated five times, to the SDRAM.

```

/*added for demo, place after the last #define statement in spl.c */
#define ROTATE_RIGHT(X) ( (X>>1) | (X&1?0X80000000:0) )
/*added for demo, place after the calibration code */
test_data_walk0((long *)0x100000,PHYS_SDRAM_1_SIZE);
int test_data_walk0(long *base, long maxsize)
{
    volatile long *addr;
    long cnt;
    ulong data_temp[3];
    ulong expected_data[3];
    ulong read_data;
    int i = 0; //counter to loop different data pattern
    int num_address;

    num_address=50;

    data_temp[0]=0xFFFFFFFF; //initial data for walking 0 pattern
    data_temp[1]=0X00000001; //initial data for walking 1 pattern
    data_temp[2]=0XAAAAAAAA; //initial data for A->5 switching

    expected_data[0]=0xFFFFFFFF; //initial data for walking 0 pattern
    expected_data[1]=0X00000001; //initial data for walking 1 pattern
    expected_data[2]=0XAAAAAAAA; //initial data for A->5 switching

    for (i=0;i<3;i++) {

printf("\nSTARTED %08X DATA PATTERN !!!!\n",data_temp[i]);
/*write*/
for (cnt = (0+i*num_address); cnt < ((i+1)*num_address) ; cnt++ ) {
    addr = base + cnt; /* pointer arith! */
    sync ();
    *addr = data_temp[i];
    data_temp[i]=ROTATE_RIGHT(data_temp[i]);
    }

/*read*/
for (cnt = (0+i*num_address); cnt < ((i+1)*num_address) ; cnt = cnt++ ) {
    addr = base + cnt; /* pointer arith! */
    sync ();
    read_data=*addr;
    printf("Address:%X Expected: %08X Read:%08X \n",addr,
expected_data[i],read_data);
    if (expected_data[i] !=read_data) {
        puts("!!!!!!FAILED!!!!!!\n\n");
        hang();
    }
    expected_data[i]=ROTATE_RIGHT(expected_data[i]);
}
}
}
}
====//End Of Code//====

```

SDRAM Controller Module Register Descriptions

Address map for the SDRAM controller and multi-port front-end. All registers in this group reset to zero.

Offset: 0x5000

[ctrlcfg](#) on page 12-45

The Controller Configuration Register determines the behavior of the controller.

[dramtiming1](#) on page 12-48

This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

[dramtiming2](#) on page 12-49

This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

[dramtiming3](#) on page 12-50

This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

[dramtiming4](#) on page 12-50

This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

[lowpwrtiming](#) on page 12-51

This register controls the behavior of the low power logic in the controller.

dramodt on page 12-52

This register controls which ODT pin asserts with chip select 0 (CS0) assertion and which ODT pin asserts with chip select 1 (CS1) assertion.

dramaddrw on page 12-53

This register configures the width of the various address fields of the DRAM. The values specified in this register must match the memory devices being used.

dramifwidth on page 12-54

This register controls the interface width of the SDRAM controller.

dramsts on page 12-55

This register provides the status of the calibration and ECC logic.

dramintr on page 12-56

This register can enable, disable and clear the SDRAM error interrupts.

sbecount on page 12-57

This register tracks the single-bit error count.

dbecount on page 12-58

This register tracks the double-bit error count.

erraddr on page 12-58

This register holds the address of the most recent ECC error.

dropcount on page 12-59

This register holds the address of the most recent ECC error.

dropaddr on page 12-60

This register holds the last dropped address.

lowpwreq on page 12-60

This register instructs the controller to put the DRAM into a power down state. Note that some commands are only valid for certain memory types.

lowpwrack on page 12-61

This register gives the status of the power down commands requested by the Low Power Control register.

staticcfg on page 12-62

This register controls configuration values which cannot be updated during active transfers. First configure the `membl` and `eccn` fields and then re-write these fields while setting the `applycfg` bit. The `applycfg` bit is write only.

ctrlwidth on page 12-63

This register controls the width of the physical DRAM interface.

portcfg on page 12-64

Each bit of the `autopchen` field maps to one of the control ports. If a port executes mostly sequential memory accesses, the corresponding `autopchen` bit should be 0. If the port has highly random accesses, then its `autopchen` bit should be set to 1.

fpgaportrst on page 12-66

This register implements functionality to allow the CPU to control when the MPFE will enable the ports to the FPGA fabric.

protportdefault on page 12-67

This register controls the default protection assignment for a port. Ports which have explicit rules which define regions which are illegal to access should set the bits to pass by default. Ports which have explicit rules which define legal areas should set the bit to force all transactions to fail. Leaving this register to all zeros should be used for systems which do not desire any protection from the memory controller.

protruleaddr on page 12-68

This register is used to control the memory protection for port 0 transactions. Address ranges can either be used to allow access to memory regions or disallow access to memory regions. If TrustZone is being used, access can be enabled for protected transactions or disabled for unprotected transactions. The default state of this register is to allow all access. Address values used for protection are only physical addresses.

protruleid on page 12-69

This register configures the AxID for a given protection rule.

protruledata on page 12-70

This register configures the protection memory characteristics of each protection rule.

protrulerdwr on page 12-71

This register is used to perform read and write operations to the internal protection table.

mppriority on page 12-72

This register is used to configure the DRAM burst operation scheduling.

remappriority on page 12-73

This register applies another level of port priority after a transaction is placed in the single port queue.

Port Sum of Weight Register Register Descriptions on page 12-74

This register is used to configure the DRAM burst operation scheduling.

ctrlcfg

The Controller Configuration Register determines the behavior of the controller.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25000

Offset: 0x5000

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

ctrlcfg Fields

Bit	Name	Description	Access	Reset
25	bursttermen	Set to a one to enable the controller to issue burst terminate commands. This must only be set when the DRAM memory type is LPDDR2.	RW	0x0
24	burstintren	Set to a one to enable the controller to issue burst interrupt commands. This must only be set when the DRAM memory type is LPDDR2.	RW	0x0
23	nodmpins	Set to a one to enable DRAM operation if no DM pins are connected.	RW	0x0
22	dgstrken	Enables DQS tracking in the PHY.	RW	0x0
21:16	starvelimit	Specifies the number of DRAM burst transactions an individual transaction will allow to reorder ahead of it before its priority is raised in the memory controller.	RW	0x0
15	reorderen	This bit controls whether the controller can re-order operations to optimize SDRAM bandwidth. It should generally be set to a one.	RW	0x0
14	gendbe	Enable the deliberate insertion of double bit errors in data written to memory. This should only be used for testing purposes.	RW	0x0
13	gensbe	Enable the deliberate insertion of single bit errors in data written to memory. This should only be used for testing purposes.	RW	0x0

Bit	Name	Description	Access	Reset															
12	cfg_enable_ecc_code_overwrites	Set to a one to enable ECC overwrites. ECC overwrites occur when a correctable ECC error is seen and cause a new read/modify/write to be scheduled for that location to clear the ECC error.	RW	0x0															
11	ecccorren	Enable auto correction of the read data returned when single bit error is detected.	RW	0x0															
10	eccen	Enable the generation and checking of ECC. This bit must only be set if the memory connected to the SDRAM interface is 24 or 40 bits wide. If you set this, you must clear the useeccasdata field in the staticcfg register.	RW	0x0															
9:8	addrorder	<p>This bit field selects the order for address interleaving. Programming this field with different values gives different mappings between the AXI or Avalon-MM address and the SDRAM address. Program this field with the following binary values to select the ordering.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> <th>Address Interleaving</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>chip, row, bank, column</td> <td>Bank interleaved with no rank (chip select) interleaving</td> </tr> <tr> <td>0x1</td> <td>chip, bank, row, column</td> <td>No interleaving</td> </tr> <tr> <td>0x2</td> <td>row, chip, bank, column</td> <td>Bank interleaved with rank (chip select) interleaving</td> </tr> <tr> <td>0x3</td> <td>reserved</td> <td>N/A</td> </tr> </tbody> </table> <p>Intel recommends programming addrorder to 0x0 or 0x2.</p>	Value	Description	Address Interleaving	0x0	chip, row, bank, column	Bank interleaved with no rank (chip select) interleaving	0x1	chip, bank, row, column	No interleaving	0x2	row, chip, bank, column	Bank interleaved with rank (chip select) interleaving	0x3	reserved	N/A	RW	0x0
Value	Description	Address Interleaving																	
0x0	chip, row, bank, column	Bank interleaved with no rank (chip select) interleaving																	
0x1	chip, bank, row, column	No interleaving																	
0x2	row, chip, bank, column	Bank interleaved with rank (chip select) interleaving																	
0x3	reserved	N/A																	
7:3	membl	Configures burst length as a static decimal value. Legal values are valid for JEDEC allowed DRAM values for the DRAM selected in cfg_type. For DDR3, this should be programmed with 8 (binary "01000"), for DDR2 it can be either 4 or 8 depending on the exact DRAM chip. LPDDR2 can be programmed with 4, 8, or 16 and LPDDR can be programmed with 2, 4, or 8. You must also program the membl field in the staticcfg register.	RW	0x0															

Bit	Name	Description	Access	Reset														
2:0	memtype	This bit field selects the memory type. This field can be programmed with the following binary values: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Reserved</td> </tr> <tr> <td>0x1</td> <td>Memory type is DDR2 SDRAM</td> </tr> <tr> <td>0x2</td> <td>Memory type is DDR3 SDRAM</td> </tr> <tr> <td>0x3</td> <td>reserved</td> </tr> <tr> <td>0x4</td> <td>Memory type is LPDDR2 SDRAM</td> </tr> <tr> <td>0x5-0x7</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Description	0x0	Reserved	0x1	Memory type is DDR2 SDRAM	0x2	Memory type is DDR3 SDRAM	0x3	reserved	0x4	Memory type is LPDDR2 SDRAM	0x5-0x7	Reserved	RW	0x0
Value	Description																	
0x0	Reserved																	
0x1	Memory type is DDR2 SDRAM																	
0x2	Memory type is DDR3 SDRAM																	
0x3	reserved																	
0x4	Memory type is LPDDR2 SDRAM																	
0x5-0x7	Reserved																	

dramtiming1

dramsts Fields

Bit	Name	Description	Access	Reset
4	corrdrop	This bit is set to 1 when any auto-corrections have been dropped.	RW	0x0
3	dbeerr	This bit is set to 1 when any ECC double bit errors are detected.	RW	0x0
2	sbeerr	This bit is set to 1 when any ECC single bit errors are detected.	RW	0x0
1	calfail	This bit is set to 1 when the PHY is unable to calibrate.	RW	0x0
0	calsuccess	This bit will be set to 1 if the PHY was able to successfully calibrate.	RW	0x0

dramintr

This register can enable, disable and clear the SDRAM error interrupts.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2503C

Offset: 0x503C

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											intrc lr	corr drop mask	dbema sk	sbema sk	intren
											RW 0x0	RW 0x0	RW 0x0	RW 0x0	RW 0x0

dramintr Fields

Bit	Name	Description	Access	Reset
4	intrclr	Writing to this self-clearing bit clears the interrupt signal. Writing to this bit also clears the error count and error address registers: sbecount, dbecount, dropcount, erraddr, and dropaddr.	RW	0x0
3	corrddropmask	Set this bit to a one to mask interrupts for an ECC correction write back needing to be dropped. This indicates a burst of memory errors in a short period of time.	RW	0x0
2	dbemask	Mask the double bit error interrupt.	RW	0x0
1	sbemask	Mask the single bit error interrupt.	RW	0x0
0	intren	Enable the interrupt output.	RW	0x0

sbecount

This register tracks the single-bit error count.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25040

Offset: 0x5040

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

corrdropaddr RW 0x0															

dropaddr Fields

Bit	Name	Description	Access	Reset
31:0	corrdropaddr	This register gives the last address which was dropped.	RW	0x0

lowpwreq

This register instructs the controller to put the DRAM into a power down state. Note that some commands are only valid for certain memory types.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25054

Offset: 0x5054

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										selfrfshmask	selfrshreq	deppwrnmask	deppwrnreq		
										RW 0x0	RW 0x0	RW 0x0	RW 0x0		

lowpwrack Fields

Bit	Name	Description	Access	Reset
5:4	selfrfshmask	Write a one to each bit of this field to have a self refresh request apply to both chips.	RW	0x0
3	selfrshreq	Write a one to this bit to request the RAM be put into a self refresh state. This bit is treated as a static value so the RAM will remain in self-refresh as long as this register bit is set to a one. This power down mode can be selected for all DRAMs supported by the controller.	RW	0x0
2:1	deppwrnmask	Write ones to this register to select which DRAM chip selects will be powered down. Typical usage is to set both of these bits when deppwrnreq is set but the controller does support putting a single chip into deep power down and keeping the other chip running.	RW	0x0
0	deppwrnreq	Write a one to this bit to request a deep power down. This bit should only be written with LPDDR2 DRAMs, DDR3 DRAMs do not support deep power down.	RW	0x0

lowpwrack

This register gives the status of the power down commands requested by the Low Power Control register.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25058

Offset: 0x5058

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

Reserved		portrstn RW 0x0													

fpgaportrst Fields

Bit	Name	Description	Access	Reset
13:0	portrstn	This register should be written to with a 1 to enable the selected FPGA port to exit reset. Writing a bit to a zero will stretch the port reset until the register is written. Read data ports are connected to bits 3:0, with read data port 0 at bit 0 to read data port 3 at bit 3. Write data ports 0 to 3 are mapped to 4 to 7, with write data port 0 connected to bit 4 to write data port 3 at bit 7. Command ports are connected to bits 8 to 13, with command port 0 at bit 8 to command port 5 at bit 13. Expected usage would be to set all the bits at the same time but setting some bits to a zero and others to a one is supported.	RW	0x0

protportdefault

This register controls the default protection assignment for a port. Ports which have explicit rules which define regions which are illegal to access should set the bits to pass by default. Ports which have explicit rules which define legal areas should set the bit to force all transactions to fail. Leaving this register to all zeros should be used for systems which do not desire any protection from the memory controller.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2508C

Offset: 0x508C

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved							portdefault RW 0x0								

protportdefault Fields

Bit	Name	Description	Access	Reset
9:0	portdefault	<p>Determines the default action for specified transactions. When a bit is zero, the specified access is allowed by default. When a bit is one, the specified access is denied by default.</p> <p>Bit 9 CPU write Bit 8 L3 write Bit 7 CPU read Bit 6 L3 read Bit 5 Access to FPGA-to-SDRAM port 5 Bit 4 Access to FPGA-to-SDRAM port 4 Bit 3 Access to FPGA-to-SDRAM port 3 Bit 2 Access to FPGA-to-SDRAM port 2 Bit 1 Access to FPGA-to-SDRAM port 1 Bit 0 Access to FPGA-to-SDRAM port 0</p>	RW	0x0

protruleaddr

This register is used to control the memory protection for port 0 transactions. Address ranges can either be used to allow access to memory regions or disallow access to memory regions. If TrustZone is being used, access can be enabled for protected transactions or disabled for unprotected transactions. The default state of this register is to allow all access. Address values used for protection are only physical addresses.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25090

Offset: 0x5090

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

The hard processor system (HPS) contains two types of on-chip memory. The on-chip memory types are:

- On-chip RAM—The on-chip RAM provides 64 KB of general-purpose RAM
- Boot ROM—The boot ROM contains the code required to boot the HPS from cold or warm reset

Both on-chip memories connect to the level 3 (L3) interconnect.

The hard processor system (HPS) contains on-chip RAM. The on-chip RAM provides 64 KB of general-purpose single-port RAM and connects to the level 3 (L3) interconnect.

Related Information

- [On-Chip RAM](#) on page 13-1
- [Boot ROM](#) on page 13-3

On-Chip RAM

Features of the On-Chip RAM

The on-chip RAM offers the following features:

- 64-bit slave interface
- 64 KB of single-ported RAM
- Read acceptance of two, write acceptance of two, and a total acceptance of four
- Error correction code (ECC) support
- High throughput - read or write every clock cycle.

Related Information

[Clock Manager](#) on page 3-1

On-Chip RAM Block Diagram and System Integration

Transfers between memory and the NIC-301 L3 interconnect happen through a 64-bit interface, gated by the `l3_main_clk` interconnect clock. ECC logic detects single-bit, corrected and double-bit, uncorrected errors. For memory, read acceptance is two, write acceptance is two, and total acceptance is two with a round-robin arbitration.

The entire RAM is either secure or non-secure. Security is enforced by the NIC-301 L3 interconnect.

Figure 13-1: On-Chip RAM Block Diagram

Note: You must initialize the on-chip RAM before you enable the ECC support to prevent false ECC interrupts triggered by uninitialized bits.

Functional Description of the On-Chip RAM

The on-chip RAM uses an 64-bit slave interface. The slave interface supports transfers between memory and the NIC-301 L3 interconnect. All reads and writes are serviced in order.

Related Information

[Clock Manager](#) on page 3-1

On-Chip RAM Clocks

The on-chip RAM is driven by the `l3_main_clk` interconnect clock.

The on-chip RAM uses an 64-bit slave interface. The slave interface supports transfers between memory and the NIC-301 L3 interconnect. All reads and writes are serviced in order.

On-Chip RAM Resets

On-Chip RAM Initialization

You must initialize the on-chip RAM before you enable the ECC. Failure to do so triggers spurious interrupts.

Follow these steps to enable ECC:

1. Turn on the ECC hardware, but disable the interrupts.
2. Initialize the SRAM in the NAND.
3. Clear the ECC event bits, because these bits may have become asserted after Step 1.
4. Enable the ECC interrupts now that the ECC bits have been set.

Initialize the on-chip RAM using the following steps:

- Disable ECC interrupts
- Enable ECC generation
- Initialize memory by clearing the contents by writing 0x0 in the address space
- Enable ECC interrupts

The hard processor system (HPS) provides a NAND flash controller to interface with external NAND flash memory in Intel system-on-a-chip (SoC) systems. You can use external flash memory to store software, or as extra storage capacity for large applications or user data. The HPS NAND flash controller is based on the CadenceDesign IP* NAND Flash Memory Controller.

NAND Flash Controller Features

The NAND flash controller provides the following functionality and features:

- Supports one x8 NAND flash device
- Supports Open NAND Flash Interface (ONFI) 1.0
- Supports NAND flash memories from Hynix, Samsung, Toshiba, Micron, STMicroelectronics, and Spansion

Note: The Spansion S34ML08G2 NAND flash memory is verified to work properly with the HPS.

- Supports error correction codes (ECCs) providing single-bit error correction and double-bit error detection, with:
 - Sector size programmable 512 byte (4-, 8-, or 16-bit correction) or 1024 byte (24-bit correction)
 - Three NAND FIFOs - ECC Buffer, write FIFO and read FIFO
- Supports pipeline read-ahead and write commands for enhanced read and write throughput
- Supports devices with 32, 64, 128, 256, 384, or 512 pages per block
- Supports multiplane devices
- Supports page sizes of 512 bytes, 2 kilobytes (KB), 4 KB, or 8 KB
- Supports single layer cell (SLC) and multiple layer cell (MLC) devices with programmable correction capabilities
- Provides internal direct memory access (DMA)
- Provides programmable access timing

NAND Flash Controller Block Diagram and System Integration

Figure 14-1: NAND Flash Controller Block Diagram

The following figure shows integration of the NAND flash controller in the HPS.

Features of the flash controller:

- Receives commands and data from the host through memory-mapped control and data registers connected to the command and data slave interface
- The host accesses the flash controller's control and status registers (CSRs) through the register slave interface.
- Handles all command sequencing and flash device interactions
- Generates interrupts to the HPS Cortex-A9 MPCore
- The DMA master interface provides accesses to and from the flash controller through the controller's built-in DMA.

NAND Flash Controller Signal Descriptions

The HPS I/O pins support a single x8 device. The following table lists the signals:

Table 14-1: NAND Flash Interface Signals

Signal	Width	I/O	Description
ad	8	in/out	Command, address and data for the flash device
ale	1	out	Address latch enable
ce_n	1	out	Output Active-low chip enable
cle	1	out	Command latch enable
re_n	1	out	Active-low read enable signal
rb	1	in	Ready/busy signal
we_n	1	out	Active-low write enable signal
wp_n	1	out	Active-low write protect signal

Functional Description of the NAND Flash Controller

This section describes the functionality of the NAND flash controller.

Discovery and Initialization

The NAND flash controller performs a specific initialization sequence after the HPS receives power and the flash device is stable. During initialization, the flash controller queries the flash device and configures itself according to one of the following flash device types:

- ONFI 1.0-compliant devices
- Legacy (non-ONFI) NAND devices

The NAND flash controller identifies ONFI-compliant connected devices using ONFI discovery protocol, by sending the `Read ID` command. For devices that do not recognize this command (especially for 512-byte page size devices), software must write to the system manager to assert the `bootstrap_512B_device` signal to identify the device type before releasing the NAND controller from reset.

To support booting and initialization, the `rdy_busy_in` pin must be connected.

The NAND flash controller performs the following initialization steps:

1. If the system manager is asserting `bootstrap_inhibit_init`, the flash controller goes directly to [step 7](#).
2. When the device is ready, the flash controller sends the "Read ID" command to read the ONFI signature from the memory device, to determine whether an ONFI or a legacy device is connected.
3. If the data returned by the memory device has an ONFI signature, the flash controller then reads the device parameter page. The flash controller stores the relevant device feature information in internal

memory control registers, enabling it to correctly program other registers in the flash device, and goes to [step 5](#).

4. If the data does not have a valid ONFI signature, the flash controller assumes that it is a legacy (non-ONFI) device. The flash controller then performs the following steps:
 - a. Sends the `reset` command to the device
 - b. Reads the device signature information
 - c. Stores the relevant values into internal memory controller registers
5. The flash controller resets the memory device. At the same time, it verifies the width of the memory interface. The HPS supports one 8-bit NAND flash device. As a result, the flash controller always detects an 8-bit memory interface.
6. The flash controller sends the `Page Load` command to block 0, page 0 of the device, configuring direct read access, so the processor can boot from that page. The processor can start reading from the first page of the flash memory, which is the expected location of the pre-loader software.

Note: The system manager can bypass this step by asserting `bootstrap_inhibit_b0p0_load` before reset is de-asserted.
7. The flash controller sends the `reset` command to the flash.
8. The flash controller clears the `rst_comp` bit in the `intr_status0` register in the `status` group to indicate to software that the flash reset is complete.

Bootstrap Interface

The NAND flash controller provides a bootstrap interface that allows software to override the default behavior of the flash controller. The bootstrap interface contains four bits, which when set appropriately, allows the flash controller to skip the initialization phase and begin loading from flash memory immediately after reset. These bits are driven by software through the system manager. They are sampled by the NAND flash controller when the controller is released from reset.

Related Information

[System Manager](#) on page 6-1

For more information about the bootstrap interface control bits.

Bootstrap Setting Bits

The following table lists the relevant bootstrap setting bits, found in the system manager's `bootstrap` register, in the NAND flash controller register group. As an example, this table also lists recommended bootstrap settings for a 512-byte page device.

Table 14-2: Bootstrap Setting Bits

Bit	Example Value for 512-Byte Page
<code>noinit</code>	1 ⁽³¹⁾
<code>page512</code>	1
<code>noloadb0p0</code>	1

⁽³¹⁾ When this register is set, the NAND flash controller expects the host to program the related device parameter registers. For more information, refer to "Configuration by Host".

Bit	Example Value for 512-Byte Page
tworowaddr	<ul style="list-style-type: none"> • 1—flash device supports two-cycle addressing • 0—flash device support three-cycle addressing

Related Information

[Configuration by Host](#) on page 14-5

Configuration by Host

If the system manager sets `bootstrap_inhibit_init` to 1, the NAND flash controller does not perform the process described in "Discovery and Initialization". In this case, the host processor must configure the flash controller.

When performance is not a concern in the design, the timing registers can be left unprogrammed.

Related Information

For recommended configuration-by-host settings to enable the basic read, write, and erase operations for a single-plane, 512 bytes/page device.
- [Discovery and Initialization](#) on page 14-3

Recommended Bootstrap Settings for 512-Byte Page Device**Table 14-3: Recommended Bootstrap Settings for an 8-bit, 512-Byte Page Device**

Register ⁽³²⁾	Value
<code>devices_connected</code>	1
<code>device_width</code>	0 indicating an 8-bit NAND flash device
<code>number_of_planes</code>	1 indicating a single-plane device
<code>device_main_area_size</code>	The value of this register must reflect the flash device's page main area size.
<code>device_spare_area_size</code>	The value of this register must reflect the flash device's page spare area size.
<code>pages_per_block</code>	The value of this register must reflect number of pages per block in the flash device.

NAND Page Main and Spare Areas

Each NAND page has a main area and a spare area. The main area is intended for data storage. The spare area is intended for ECC and maintenance data, such as wear leveling information. Each block consists of a group of pages.

⁽³²⁾ All registers are in the `config` group.

The sizes of the main and spare areas, and the number of blocks in a page, depend on the specific NAND device connected to the NAND flash controller. Therefore, the device-dependent registers, `device_main_area_size`, `device_spare_area_size`, and `pages_per_block`, must be programmed to match the characteristics of the device.

If your software does not perform the discovery and initialization sequence, the software must include an alternative method to determine the correct value of the device-dependent registers. The HPS boot ROM code enables discovery and initialization by default (that is, `bootstrap_inhibit_init = 0`).

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers. Of the three, only the read and write clocks are asynchronous.

- **ECC buffer**—Operates at the core clock, it enables the simultaneous process between sending out the data to the host and receiving data from the device to achieve a line rate operation.
- **Write FIFO**—The write port operates at `ac1k` and the read port operates at `c1k`. The buffer must be large enough to pre-allocate all the read data associated with the number of the outstanding read requests that it could issue to the hosts. Up to 8 outstanding read requests are supported, with a maximum burst size of 64 bytes. Therefore, the write FIFO buffer is a 128×32 -bit memory (512 total bytes).
- **Read FIFO**—The read port operates at `ac1k` and the write port operates at `c1k`. Regardless of the number of outstanding read requests that it could receive from the host, it only requires a buffer size that is just enough to sustain the streaming from the device memory to the system bus. Therefore, the read FIFO buffer is a 32×32 -bit memory (128 total bytes). Since the size of the read FIFO is relatively small for SRAM implementation, it can be implemented using flops.

Clocks

To minimize the number of clocks, Clock Manager outputs software managed enables to the USB, SPI Masters, QSPI and NAND peripherals. The software enable for NAND is `nand_clk_en` and is set to ENABLE by default. Also, in Boot Mode, `nand_clk_en` is active to ensure that all clocks are active if RAM is cleared for security.

Table 14-4: Clock Inputs to NAND Flash Controller

Clock Signal	Description
<code>nand_x_clk</code>	Clock for master and slave interfaces and the ECC sector buffer.
<code>nand_clk</code>	Clock for the NAND flash controller.

The frequency of `nand_x_clk` is four times the frequency of `nand_clk`.

Clock Generation

The clock manager sends the top level clock from the HPS.

The clock manager sends the 200 MHz clock, `l4_mp_clk`, to the NAND Flash Controller. This clock becomes the NAND reference clock called `nand_mp_clk`. The `nand_mp_clk` is divided by four and is used for input and output. Since the NAND places a 200 MHz limit on the clock, each of these four generated clocks are 50 MHz and called `nand_clk`.

Clock Enable

The `nand_mp_clk` and `nand_clk` clocks have enables.

Clock Switching

When you use clock switching, you must follow the following requirements:

- Ensure that there is no activity.
- Software must disable this module during the frequency switch and re-enable it after the frequency has changed.
- When clock switching is complete, the software must reconfigure the NAND initialization registers according to the new frequency before triggering any new transactions onto the flash interface.

Resets

The NAND flash controller has one reset signal, `nand_flash_rst_n`. The reset manager drives this signal to the NAND flash controller on a cold or warm reset.

Related Information

[Reset Manager](#) on page 4-1

Taking the NAND Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

- [Module Reset Signals](#) on page 4-5
- [Modules Requiring Software Deassert](#) on page 4-9

Indexed Addressing

The NAND flash controller uses indexed addressing to reduce the address span consumed by the flash controller.

Indirect addressing is implemented by two registers, accessed through the `nanddata` region, as described in the "Register Map for Indexed Addressing" section.

Register Map for Indexed Addressing

Indexed addressing uses registers in the `nanddata` region of the HPS memory map. The `nanddata` region consists of a control register and a variable-size register that allows direct access to flash memory, as detailed in the following table.

Table 14-5: Register Map for Indexed Addressing

Register Name	Offset Address	Usage
Control	0x0	Identifies the page of flash memory to be read or written. Software writes the 32-bit control information consisting of map command type, block, and page address. The upper four bits must be set to 0. For specific usage of the <code>Control</code> register, refer to "Command Mapping".
Data	0x10	The <code>Data</code> register is a page-size window into the NAND flash. By reading from or writing to locations starting at this offset, the software reads directly from or writes directly to the page and block of NAND flash memory specified by the <code>Control</code> register. The <code>Data</code> register is always addressed on 32-bit word boundaries, although the physical flash device has an 8-bit-wide data path.

Related Information

- [Command Mapping](#) on page 14-8
- [HPS Peripheral Region Address Map](#) on page 2-17

Indexed Addressing Host Usage

The host uses indexed addressing as follows:

1. Program the 32-bit index-address field into the `Control` register in the `nanddata` region. This action provides the flash address parameters to the NAND flash controller.
2. Perform a 32-bit read or write in the `Data` register.
3. Perform additional 32-bit reads and writes if they are in the same page and block in flash memory.

It is unnecessary to write to the control register for every data transfer if a group of data transfers targets the same page and block address. For example, you can write the control register at the beginning of a page with the block and page address, and then read or write the entire page by directing consecutive transactions to the `Data` register.

Command Mapping

The NAND flash controller supports several flash controller-specific MAP commands, providing an abstraction level for programming a NAND flash device. By using the MAP commands, you can avoid directly programming device-specific commands. Using this abstraction layer provides enhanced performance. Commands take multiple cycles to send off-chip. The MAP commands let you initiate commands and let the flash controller sequence them off-chip to the NAND device.

The NAND flash controller supports the following flash controller-specific MAP commands:

- MAP00 commands—boot-read or buffer read/write during read-modify-write operations
- MAP01 commands—memory arrays read/write
- MAP10 commands—NAND flash controller commands
- MAP11 commands—low-level direct access

MAP00 Commands

MAP00 commands access a page buffer in the NAND flash device. Addressing always begins at 0x0 and extends to the page size specified by the `device_main_area_size` and `device_spare_area_size` registers in the `config` group. You can use this command to perform a boot read. Use MAP00 commands in read-modify-write (RMW) operations to read or write any word in the buffer. MAP00 commands allow a direct data path to the page buffer in the device.

The host can access the page buffer directly using the MAP00 commands only if there are no other MAP01 or MAP10 commands active on the NAND flash controller.

MAP00 Command Format

Table 14-6: MAP00 Command Format with Address Mapping

The following table shows the format of a MAP00 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 0
25:13	(reserved)	Set to 0
12:2	BUFF_ADDR	Data width-aligned buffer address on the memory device. Maximum page access is 8 KB.
1:0	(reserved)	Set to 0

MAP00 Usage Limitations

The usage of these commands under normal operations is limited to the following situations:

- They can be used to perform an Execute-in-Place (XIP) boot from the device; reading directly from the page buffer while booting directly from the device.
- MAP00 commands can be used to perform RMW operations where MAP00 writes are used to modify a read page in the device page buffer. Because the NAND flash controller does not perform ECC correction during such an operation, Intel does not recommend this method in an MLC device.
- In association with MAP11 commands, MAP00 commands provide a way for the host to directly access the device bypassing the hardware abstractions provided by NAND flash controller with MAP01 and MAP10 commands. This method is also used for debugging, or for issuing an operation that the flash controller might not support with MAP01 or MAP10 commands.

Restrictions:

- MAP00 commands cannot be used with MAP01 commands to read part of a page. Accesses using MAP01 commands must perform a complete page transfer.
- No ECC is performed during a MAP00 data access.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while performing MAP00 operations.

MAP01 Commands

MAP01 commands transfer complete pages between the host memory and a specific page of the NAND flash device. Because the MAP01 commands support only page addresses, the entire page must be read or written at once. The actual number of commands required depends on the size of the data transfer. The Command register points to the first page and block in the transfer. You do not change the Command register when you initiate subsequent transactions in the transfer, but only when the entire page is transferred.

When the NAND flash controller receives a read command, it issues a load operation on the device, waits for the load to complete, and then returns read data. Read data must be read from the start of the page to the end of the page.

Write data must be written from the start of the page to the end of the page. When the NAND flash controller receives confirmation of the transfer, it issues commands to program the data into the device.

The flash controller ignores the byte enables for read and write commands and transfers the entire data width.

MAP01 Command Format

Table 14-7: MAP01 Command Format with Address Mapping

The following table shows the format of a MAP01 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 1
25:24	(reserved)	Set to 0
23:<M>	BLK_ADDR	Block address in the device
(<M>-1):0	PAGE_ADDR	Page address in the device

Note: <M> depends on the number of pages per block in the device. $\langle M \rangle = \text{ceil}(\log_2(\langle \text{device pages per block} \rangle))$. Therefore, use the following values:

- 32 pages per block: $\langle M \rangle = 5$
- 64 pages per block: $\langle M \rangle = 6$
- 128 pages per block: $\langle M \rangle = 7$
- 256 pages per block: $\langle M \rangle = 8$
- 384 pages per block: $\langle M \rangle = 9$
- 512 pages per block: $\langle M \rangle = 9$

MAP01 Usage Limitations

Use the MAP01 command as follows:

- A complete page must be read or written using a MAP01 command. During such transfers, every transaction from the host must have the same block and page address. The NAND flash controller internally keeps track of how much data it reads or writes.
- MAP00 commands cannot be used in between using MAP01 commands for reading or writing a page.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while the host is performing MAP01 operations directly. If the host issues MAP01 commands to the NAND flash controller while DMA is enabled, the flash controller discards the request and generates an `unsup_cmd` interrupt.

MAP10 Commands

MAP10 commands provide an interface to the control plane of the NAND flash controller. MAP10 commands control special functions of the flash device, such as erase, lock, unlock, copy back, and page spare area access. Data passed in this command pathway targets the NAND flash controller rather than the flash device. Unlike other command types, the data (input or output) related to these transactions does not affect the contents of the flash device. Rather, this data specifies and performs the exact commands of the flash controller. Only the lower 16 bits of the `Data` register contain the relevant information.

MAP10 Command Format

Table 14-8: MAP10 Command Format with Address Mapping

The following table shows the format of a MAP10 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 2
25:24	(reserved)	Set to 0
23:<M>	BLK_ADDR	Block address in the device
(<M>-1):0	PAGE_ADDR	Page address in the device

Note: <M> depends on the number of pages per block in the device, as follows:

- 32 pages per block: <M>=5
- 64 pages per block: <M>=6
- 128 pages per block: <M>=7
- 256 pages per block: <M>=8
- 384 pages per block: <M>=9
- 512 pages per block: <M>=9

MAP10 Operations

Table 14-9: MAP10 Operations

Command	Function
0x01	Sets block address for erase and initiates operation
0x10	Sets unlock start address
0x11	Sets unlock end address and initiates unlock
0x21	Initiates a lock of all blocks
0x31	Initiates a lock-tight of all blocks
0x41	Sets up for spare area access
0x42	Sets up for default area access
0x43	Sets up for main+spare area access
0x60	Loads page to the buffer for a RMW operation
0x61	Sets the destination address for the page buffer in RMW operation
0x62	Writes the page buffer for a RMW operation
0x1000	Sets copy source address
0x11<PP>	Sets copy destination address and initiates a copy of <PP> pages
0x20<PP>	Sets up a pipeline read-ahead of <PP> pages
0x21<PP>	Sets up a pipeline write of <PP> pages

MAP10 Usage Limitations

Use the MAP10 commands as follows:

- MAP10 commands should be used to issue commands to the controller, such as erase, copy-back, lock, or unlock.
- MAP10 pipeline commands should also be used to read or write consecutive multiple pages from the flash device within a device block boundary. The host must first issue a MAP10 pipeline read or write command and then issue MAP01 commands to do the actual data transfers. The MAP10 pipeline read or write command instructs the NAND flash controller to use high-performance commands such as cache or multiplane because the flash controller has knowledge of multiple consecutive pages to be read. The pages must not cross a block boundary. If a block boundary is crossed, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Up to four pipeline read or write commands, at the same time, can be issued to the NAND flash controller.
- While the NAND flash controller is performing MAP10 pipeline read or write commands, DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0). DMA must be disabled because the host is directly transferring data from and to the flash device through the flash controller.

MAP11 Commands

MAP11 commands provide direct access to the NAND flash controller’s address and control cycles, allowing software to issue the commands directly to the flash device using the Command and Data registers. The MAP11 command is useful if the flash device supports a device-specific command not included with standard flash commands. It can also be useful for low-level debugging.

MAP11 commands provide a direct control path to the flash device. These commands execute command, address, and data read and write cycles directly on the NAND device interface. The host can issue only single-beat accesses to the `nanddata` region while using MAP11 commands. The following are the usage requirements:

- Command, address, and write data values are placed in the `Data` register.
- Command and address cycles to the device must be a write transaction on the host bus.
- For data cycles, the type of transaction on the host bus (read/write) determines the data cycle type on the device interface.
- On a read, the returned data also appears in the `Data` register.
- The Control register encodes the control operation type.

MAP11 Control Format

Table 14-10: MAP11 Control Format with Address Mapping

The following table shows the format of a MAP11 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	<code>CMD_MAP</code>	Set to 3
25:2	(reserved)	Set to 0

Address Bits	Name	Description
1:0	TYPE	Sets the control type as follows: <ul style="list-style-type: none"> • 0 = Command cycle • 1 = Address cycle • 2 = Data Read/Write Cycle

MAP11 Usage Limitations

Use the MAP11 commands as follows:

- Use MAP11 commands only in special cases, for debugging or sending device-specific commands that are not supported by the NAND flash controller.
- DMA must be disabled before you use MAP11 operations.
- The host can use only single beat access transfers when using MAP11 commands.

Note: MAP11 commands provide direct, unstructured access to the NAND flash device. Incorrect use can lead to unpredictable behavior.

Data DMA

The DMA transfers data with minimal host involvement. Software initiates data DMA with the MAP10 command.

The `flag` bit of the `dma_enable` register in the `dma` group enables data DMA functionality. Only enable or disable this functionality when there are no active transactions pending in the NAND flash controller. When the DMA is enabled, the flash controller initiates one DMA transfer per MAP10 command over the DMA master interface. When the DMA is disabled, all operations with the flash controller occur through the memory-mapped `nanddata` region.

The NAND flash controller supports up to four outstanding DMA commands, and ignores additional DMA commands. If software issues more than four outstanding DMA commands, the flash controller issues the `unsup_cmd` interrupt. On receipt of a DMA command, the flash controller performs command sequencing to transfer the number of pages requested in the DMA command. The DMA master reads or writes page data from the system memory in programmed burst-length chunks. After the DMA command completes, the flash controller issues an interrupt, and starts working on the next queued DMA command.

Pipelining allows the NAND flash controller to optimize its performance while executing back-to-back commands of the same type.

With certain restrictions, non-DMA MAP10 commands can be issued to the NAND flash controller while the flash controller is servicing DMA transactions. MAP00, MAP01, and MAP11 commands cannot be issued while DMA mode is enabled because the flash controller is operating in an extremely tightly-coupled, high-performance data transfer mode. On receipt of erroneous commands (MAP00, MAP01 or MAP11), the flash controller issues an `unsup_cmd` interrupt to inform the host about the violating command.

Consider the following points when using the DMA:

- A data DMA command is a type of MAP10 command. This command is interpreted by the data DMA engine and not by the flash controller core.
- No MAP01, MAP00, or MAP11 commands are allowed when DMA is enabled.
- Before the flash controller can accept data DMA commands, DMA must be enabled by setting the `flag` bit of the `dma_enable` register in the `dma` group.
- When DMA is enabled and the DMA engine initiates data transfers, ECC can be enabled for as-needed data correction concurrent with the data transfer.
- MAP10 commands are used along with data movements similar to MAP01 commands.
- With the exception of data DMA commands and MAP10 pipeline read and write commands, all other MAP10 commands such as erase, lock, unlock, and copy-back are forwarded to the flash controller.
- At any time, up to four outstanding data DMA commands can be handled by flash controller. During multi-page operations, the DMA transfer must not cross a flash block boundary. If it does, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Data DMA commands are typically multi-page read and write commands with an associated pointer in host memory. The multi-page data is transferred to or from the host memory starting from the host memory pointer.
- Data DMA uses the `flash_burst_length` register in the `dma` group to determine the burst length value to drive on the interconnect. The data DMA hardware does not account for the interconnect's boundary crossing restrictions. The host must initialize the starting host address so that the DMA master burst transaction does not cross a 4 KB boundary.

There are two methods for initiating a DMA transaction: the multitransaction DMA command, and the burst DMA command.

Multi-Transaction DMA Command

The NAND flash controller processes multitransaction DMA commands only if it receives all four command-data pairs in order. The flash controller responds to out-of-order commands with an `unsup_cmd` interrupt. The flash controller also responds with an `unsup_cmd` interrupt if sequenced commands are interleaved with other flash controller MAP commands.

To initiate DMA with a multitransaction DMA command, you send four command-data pairs to the NAND flash controller through the Control and Data registers in the `nanddata` region, as shown in "Command-Data Pair Formats".

Using Multi-Transaction DMA Commands

If you want the NAND flash controller DMA to perform cacheable accesses then you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to change its cache capabilities.

You can issue non-DMA MAP10 commands while the NAND flash controller is in DMA mode. For example, you might trigger a host-initiated page move between DMA commands, to achieve wear leveling. However, do not interleave non-DMA MAP10 commands between the command-data pairs in a set of multitransaction DMA commands. You must issue all four command-data pairs shown in the above tables before sending a different command.

Note: Do not issue MAP00, MAP01 or MAP11 commands while DMA is enabled.

MAP10 commands in multitransaction format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in increment four (INCR4) format (described in "Burst DMA Command").

Related Information

- [Indexed Addressing](#) on page 14-7
- [Burst DMA Command](#) on page 14-17
- [System Manager](#) on page 6-1

Burst DMA Command

You can initiate a DMA transfer by sending a command to the NAND flash controller as a burst transaction of four 16-bit accesses. This form of DMA command might be useful for initiating DMA transfers from custom IP in the FPGA fabric. Most processor cores cannot use this form of DMA command, because they cannot control the width of the burst.

When DMA is enabled, the NAND flash controller recognizes the MAP10 pipeline DMA command as an INCR4 command, in the format shown in the following table. The address decoding for MAP10 pipeline DMA command remains the same, as shown in "MAP10 Command Format".

⁽³⁵⁾ INT specifies the host interrupt to be generated at the end of the complete DMA transfer. For more information about INT, see the Note at the bottom of this table.

⁽³⁶⁾ Can be only 4, 16, 32, or 64 bytes. No other values are valid.

MAP10 commands in INCR4 format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in multitransaction format (described in the "Multi-Transaction DMA Command").

Table 14-15: MAP10 Burst DMA (INCR4) Command Structure

The following table lists the MAP10 burst DMA command structure. The burst DMA command carries the same information as the multi-transaction DMA command-data pairs, but in a very different format.

Data Beat	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Beat 2 ⁽³⁷⁾	Memory address low															
Beat 3	0x0							INT ⁽³⁸⁾		Burst length						

Note: INT controls the value of the `dma_cmd_comp` bit of the `intr_status0` register in the `status` group at the end of the DMA transfer. INT can take on one of the following values:

0—Do not interrupt host. The `dma_cmd_comp` bit is set to 0.

1—Interrupt host. The `dma_cmd_compp` bit is set to 1.

You can optionally send the 16-bit fields in the above table to the NAND flash controller as four separate bursts of length 1 in sequential order. Intel recommends this method.

If you want the NAND flash controller DMA to perform cacheable accesses, you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to modify its cache capabilities.

ECC

The NAND flash controller incorporates ECC logic to calculate and correct bit errors. The flash controller uses a Bose-Chaudhuri-Hocquenghem (BCH) algorithm for detection of multiple errors in a page.

The NAND flash controller supports 512- and 1024-byte ECC sectors. The flash controller inserts ECC check bits for every 512 or 1024 bytes of data, depending on the selected sector size. After 512 or 1024 bytes, the flash controller writes the ECC check bit information to the device page.

ECC information is striped in between 512 or 1024 bytes of data across the page. The NAND flash controller reads ECC information in the same pattern and performs a calculation to check for the presence of errors.

⁽³⁷⁾ The buffer address in host memory, which must be aligned to 32 bits.

⁽³⁸⁾ INT specifies the host interrupt to be generated at the end of the complete DMA transfer. For more information about INT, see the Note at the bottom of this table.

Correction Capability, Sector Size, and Check Bit Size

Table 14-16: Correction Capability, Sector Size, and Check Bit Size

Correction	Sector Size in Bytes	Check Bit Size in Bytes
4	512	8
8	512	14
16	512	26
24	1024	42

ECC Programming Modes

The NAND flash controller provides the following ECC programming modes that software uses to format a page:

- Main Area Transfer Mode
- Spare Area Transfer Mode
- Main+Spare Area Transfer Mode

Related Information

- [Main Area Transfer Mode](#) on page 14-19
- [Spare Area Transfer Mode](#) on page 14-19
- [Main+Spare Area Transfer Mode](#) on page 14-20

Main Area Transfer Mode

In main area transfer mode, when ECC is enabled, the NAND flash controller inserts ECC check bits in the data stream on writes and strips ECC check bits on reads. Software does not need to manage the ECC sectors when writing a page. ECC checking is performed by the flash controller, so software simply transfers the data.

If ECC is turned off, the NAND flash controller does not read or write ECC check bits.

Figure 14-2: Main Area Transfer Mode for ECC

Spare Area Transfer Mode

The NAND flash controller does not introduce or interpret ECC check bits in spare area transfer mode, and acts as a pass-through for data transfer.

Figure 14-3: Spare Area Transfer Mode for ECC

Main+Spare Area Transfer Mode

In main+spare area transfer mode, the NAND flash controller expects software to format a page as shown in following figure. When ECC is enabled during a write operation, the flash controller-generated ECC check bits replace the ECC check bit data provided by software. During read operations, the flash controller forwards the ECC check bits from the device to the host. If ECC is disabled, page data received from the software is written to the device, and read data received from the device is forwarded to the host.

Figure 14-4: Main+Spare Area Transfer Mode for ECC

Sector 0	ECC0	Sector 1	ECC1	Sector 2	ECC2	Sector 3	ECC3	Flags
----------	------	----------	------	----------	------	----------	------	-------

Preserving Bad Block Markers

When flash device manufacturers test their devices at the time of manufacture, they mark any bad device blocks that are found. Each bad block is marked at specific, known offsets, typically at the base of the spare area. A bad block marker is any byte value other than 0xFF (the normal state of erased flash).

Bad block markers can be overwritten by the last sector data in a page when ECC is enabled. This happens because the NAND flash controller also uses the main area of a page to store ECC information, which causes the last sector to spill over into the spare area. It is necessary for the system to preserve the bad block information prior to writing data, to ensure the correct identification of bad blocks in the flash device.

You can configure the NAND flash controller to skip over a specified number of bytes when it writes the last sector in a page to the spare area. This option allows the flash controller to preserve bad block markers. To use this option, write the desired offset to the `spare_area_skip_bytes` register in the `config` group. For example, if the device page size is 2 KB, and the device manufacturer stores the bad block markers in the first two bytes in the spare area, set the `spare_area_skip_bytes` register to 2. When the flash controller writes the last sector of the page that overlaps with the spare area, it starts at offset 2 in the spare area, skipping the bad block marker at offset 0. A value of 0 (default) specifies that no bytes are skipped. The value of `spare_area_skip_bytes` must be an even number. For example, if the bad block marker is a single byte, set `spare_area_skip_bytes` to 2.

In main area transfer mode, the NAND flash controller does not skip the bad block marker. Instead, it overrides the bad block marker with the value programmed in the `spare_area_marker` register in the `config` group. This 8-bit register is used in conjunction with the `spare_area_skip_bytes` register in the `config` group to determine which bytes in the spare area of a page should be written with a the new marker value. For example, to mark a block as good set the `spare_area_marker` register to 0xFF and set the `spare_area_skip_bytes` register to the number of bytes that the marker should be written to, starting from the base of the spare area.

In the spare area transfer mode, the NAND flash controller ignores the `spare_area_skip_bytes` and `spare_area_marker` registers. The flash controller transfers the data exactly as received from the host or device.

In the main+spare area transfer mode, the NAND flash controller starts writing the last sector in a page into the spare area, starting at the offset specified in the `spare_area_skip_bytes` register. However, the area containing the bad block identifier information is overwritten by the data the host writes into the page. The host writes both the data sectors and the bad block markers. The flash controller depends on the host software to set up the bad block markers properly before writing the data.

Figure 14-5: Bad Block Marker

The following figure shows an example of how the NAND flash controller can skip over a bad block marker. In this example, the flash device has a 2-KB page with a 64-byte spare area. A 14-byte sector ECC is shown, with 8 byte per sector correction.

Error Correction Status

The ECC error correction information (`ECCCorInfo_b01`) register, in the `ecc` group, contains error correction information for each read or write that the NAND flash controller performs. The `ECCCorInfo_b01` register contains ECC error correction information in the `max_errors_b0` and `uncor_err_b0` fields.

At the end of data correction for the transaction in progress, `ECCCorInfo_b01` holds the maximum number of corrections applied to any ECC sector in the transaction. In addition, this register indicates whether the transaction as a whole has correctable errors, uncorrectable errors, or no errors at all. A transaction has no errors when none of the ECC sectors in the transaction has any errors. The transaction is marked as uncorrectable if any one of the sectors is uncorrectable. The transaction is marked as correctable if any one sector has correctable errors and none is uncorrectable.

At the end of each transaction, the host must read this register. The value of this register provides error data to the host about the block. The host can take corrective action after the number of correctable errors encountered reaches a particular threshold value.

NAND Flash Controller Programming Model

This section describes how the NAND flash controller is to be programmed by software running on the microprocessor unit (MPU).

Note: If you write a configuration register and follow it up with a data operation that is dependent on the value of this configuration register, Intel recommends that you read the value of the register before performing the data operation. This read operation ensures that the posted write of the register is completed and takes effect before the data operation is issued to the NAND flash controller.

Basic Flash Programming

This section describes the steps that must be taken by the software to access and control the NAND flash controller.

NAND Flash Controller Optimization Sequence

The software must configure the flash device for interrupt or polling mode, using the `bank0` bit of the `rb_pin_enabled` register in the `config` group. If the device is in polling mode, the software must also program the additional registers, to select the times and frequencies of the polling. Program the following registers in the `config` group:

- Set the `rb_pin_enabled` register to the desired mode of operation for each flash device.
- For polling mode, set the `load_wait_cnt` register to the appropriate value depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `program_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `erase_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `int_mon_cycnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.

At any time, the software can change any flash device from interrupt mode to polling mode or vice-versa, using the `bank0` bit of the `rb_pin_enabled` register.

The software must ensure that the particular flash device does not have any outstanding transactions before changing the mode of operation for that particular flash device.

Device Initialization Sequence

At initialization, the host software must program the following registers in the `config` group:

- Set the `devices_connected` register to 1.
- Set the `device_width` register to 8.
- Set the `device_main_area_size` register to the appropriate value.
- Set the `device_spare_area_size` register to the appropriate value.
- Set the `pages_per_block` register according to the parameters of the flash device.
- Set the `number_of_planes` register according to the parameters of the flash device.
- If the device allows two ROW address cycles, the `flag` bit of the `two_row_addr_cycles` register must be set to 1. The host program can ensure this condition either of the following ways:
 - Set the `flag` bit of the `bootstrap_two_row_addr_cycles` register to 1 prior to the NAND flash controller's reset initialization sequence, causing the flash controller to initialize the bit automatically.
 - Set the `flag` bit of the `two_row_addr_cycles` register directly to 1.
- Clear the `chip_enable_dont_care` register in the `config` group to 0.

The NAND flash controller can identify the flash device features, allowing you to initialize the flash controller registers to interface correctly with the device, as described in *Discovery and Initialization*.

However, a few NAND devices do not follow any universally accepted identification protocol. If connected to such a device, the NAND flash controller cannot identify it correctly. If you are using such a device, your software must use other means to ensure that the initialization registers are set up correctly.

Related Information

[Discovery and Initialization](#) on page 14-3

Device Operation Control

This section provides a list of registers that you need to program while choosing to use multi-plane or cache operations on the device. If the device does not support multi-plane operations or cache operations, then these registers can be left at their power-on reset values with no impact on the functionality of the NAND flash controller. Even if the device supports these sequences, the software does not need to use them. Software can leave these registers at their power-on reset values.

Program the following registers in the `config` group to achieve the best performance from a given device:

- Set `flag` bit in the `multiplane_operation` register in the `config` group to 1 if the device supports multi-plane operations to access the data on the flash device connected to the NAND flash controller. If the flash controller is set up for multi-plane operations, the number of pages to be accessed is always a multiple of the number of planes in the device.
- If the NAND flash controller is configured for multi-plane operation, and if the device has support for multi-plane read command sequence, set the `multiplane_read_enable` register in the `config` group.
- If the device implements multiplane address restrictions, set the `flag` bit in the `multiplane_addr_restrict` register to 1.
- Initialize the `die_mask` and `first_block_of_next_plane` registers as per device requirements.
- If the device supports cache command sequences, enable the `cache_write_enable` and `cache_read_enable` registers in the `config` group.
- Clear the `flag` bit of the `copyback_disable` register in the `config` group to 0 if the device does not support the copyback command sequences. The register defaults to enabled state.
- The `read_mode`, `write_mode` and `copyback_mode` registers, in the `config` group, currently need not be written by software, because the NAND flash controller is capable of using the correct sequences based on a combination of some multi-plane or cache-related settings of the NAND flash controller and the manufacturer ID. If at some future time these settings change, program the registers to accommodate the change.

ECC Enabling

Before you start any data operation on the flash device, you must decide whether you want the ECC enabled or disabled.

Initialize the memory data before you enable ECC the first time, to prevent spurious ECC.

Follow these steps to enable ECC:

1. Turn on the ECC hardware, but disable the interrupts.
2. Initialize the SRAM in the NAND.
3. Clear the ECC event bits, because these bits may have become asserted after Step 1.
4. Enable the ECC interrupts now that the ECC bits have been set.

If the ECC needs enabling, set up the appropriate correction level depending on the page size and the spare area available on the device.

Set the `flag` bit in the `ecc_enable` register in the `config` group to 1 to enable ECC. If enabled, the following registers in the `config` group must be programmed accordingly, else they can be ignored:

- Initialize the `ecc_correction` register to the appropriate correction level.
- Program the `spare_area_skip_bytes` and `spare_area_marker` registers in the `config` group if the software needs to preserve the bad block marker.

Related Information[ECC](#) on page 14-18**NAND Flash Controller Performance Registers**

These registers specify the size of the bursts on the device interface, which maximizes the overall performance on the NAND flash controller.

Initialize the `flash_burst_length` register in the `dma` group to a value which maximizes the performance of the device interface by minimizing the number of bursts required to transfer a page.

Interrupt and DMA Enabling

Prior to initiating any data operation on the NAND flash controller, the software must set appropriate interrupt status register bits. If the software uses the DMA logic in the flash controller, then the appropriate DMA enable and interrupts bits in the register space must be set.

1. Set the `flag` bit in the `global_int_enable` register in the `config` group to 1, to enable global interrupt.
2. Set the relevant bits of the `intr_en0` register in the `status` group to 1 before initiating any operations if the flash controller is in interrupt mode. Intel recommends that the software reads back this register to ensure clearing an interrupt status. This recommendation applies also to an interrupt service routine.
3. Enable DMA if your application needs DMA mode. Enable DMA by setting the `flag` bit of the `dma_enable` register in the `dma` group. Intel recommends that the software reads back this register to ensure that the mode change is accepted before sending a DMA command to the flash controller.
4. If the DMA is enabled, then set up the appropriate bits of the `dma_intr_en` register in the `dma` group.

Order of Interrupt Status Bits Assertion

The following interrupt status bits, in the `intr_status0` register in the `status` group, are listed in the order of interrupt bit setting:

1. `time_out`—All other interrupt bits are set to 0 when the watchdog `time_out` bit is asserted.
2. `dma_cmd_comp`—This bit signifies the completion of data transfer sequence.⁽³⁹⁾
3. `pipe_cpybck_cmd_comp`—This bit is asserted when a copyback command or the last page of a pipeline command completes.
4. `locked_blk`—This bit is asserted when a program (or erase) is performed on a locked block.
5. `INT_act`—No relationship with other interrupt status bits. Indicates a transition from 0 to 1 on the `ready_busy` pin value for that flash device.
6. `rst_comp`—No relationship with other interrupt status bits. Occurs after a reset command has completed.
7. For an erase command:
 - a. `erase_fail` (if failure)
 - b. `erase_comp`
8. For a program command:
 - a. `locked_blk` (if performed on a locked block)
 - b. `pipe_cmd_err` (if the pipeline sequence is broken by a MAP01 command)
 - c. `page_xfer_inc` (at the end of each page data transfer)
 - d. `program_fail` (if failure)

⁽³⁹⁾ This interrupt status bit is the last to be asserted during a DMA operation to transfer data.

- e. `pipe_cpybck_cmd_comp`
 - f. `program_comp`
 - g. `dma_cmd_comp` (If DMA enabled)
9. For a read command:
- a. `pipe_cmd_err` (if the pipeline sequence is broken by a MAP01 command)
 - b. `page_xfer_inc` (at the end of each page data transfer)
 - c. `pipe_cpybck_cmd_comp`
 - d. `load_comp`
 - e. `ecc_uncor_error` (if failure)
 - f. `dma_cmd_comp` (If DMA enabled)

Timing Registers

You must optimize the following registers for your flash device's speed grade and clock frequency. The NAND flash controller operates correctly with the power-on reset values. However, functioning with power-on reset values is a non-optimal mode that provides loose timing (large margins to the signals).

Set the following registers in the `config` group to optimize the NAND flash controller for the speed grade of the connected device and frequency of operation of the flash controller:

- `twhr2_and_we_2_re`
- `tcwaw_and_addr_2_data`
- `re_2_we`
- `acc_clks`
- `rdwr_en_lo_cnt`
- `rdwr_en_hi_cnt`
- `max_rd_delay`
- `cs_setup_cnt`
- `re_2_re`

Registers to Ignore

You do not need to initialize the following registers in the `config` group:

- The `transfer_spare_reg` register—Data transfer mode can be initialized using MAP10 commands.
- The `write_protect` register—Does not need initializing unless you are testing the write protection feature.

Flash-Related Special Function Operations

This section describes all the special functions that can be performed on the flash memory.

The functions are defined by MAP10 commands as described in *Command Mapping*.

Related Information

[Command Mapping](#) on page 14-8

Erase Operations

Before data can be written to flash, an erase cycle must occur. The NAND flash memory controller supports single block and multi-plane erases.

The controller decodes the block address from the indirect addressing shown in "MAP10 Command Format".

Related Information

[MAP10 Command Format](#) on page 14-11

Single Block Erase

A single command is needed to complete a single-block erase, as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For a single block erase, the register `multiplane_operation` in the `config` group must be reset.

After the device completes the erase operation, the controller generates an `erase_comp` interrupt. If the erase operation fails, the `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Multi-Plane Erase

For multi-plane erases, the `number_of_planes` register in the `config` group holds the number of planes in the flash device, and the block address specified must be aligned to the number of planes in the device. The NAND flash controller consecutively erases each block of the memory, up to the number of planes available. Issue this command as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For multi-plane erase, the register `multiplane_operation` in the `config` group must be set.

After the device completes erase operation on all planes, the NAND flash controller generates an `erase_comp` interrupt. If the erase operation fails on any of the blocks in a multi-plane erase command, an `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Lock Operations

The NAND flash controller supports the following features:

- Flash locking—The NAND flash controller supports all flash locking operations.
The flash device itself might have limited support for these functions. If the device does not support locking functions, the flash controller ignores these commands.
- Lock-tight—With the lock-tight feature, the NAND flash controller can prevent lock status from being changed. After the memory is locked tight, the flash controller must be reset before any flash area can be locked or unlocked.

Unlocking a Span of Memory Blocks

To unlock several blocks of memory, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to unlock.
2. Write 0x10 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the ending address of the area to unlock.
4. Write 0x11 to the `Data` register.

When unlocking a range of blocks, the start block address must be less than the end block address. Otherwise, the NAND flash controller exhibits undetermined behavior.

Locking All Memory Blocks

To lock the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x21 to the `Data` register.

Setting Lock-Tight on All Memory Blocks

After the lock-tight is applied, unlocked areas cannot be locked, and locked areas cannot be unlocked. To lock-tight the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x31 to the `Data` register.

To disable the lock-tight, reset the memory controller.

Transfer Mode Operations

You can configure the NAND flash controller in one of the following modes of data transfer:

- Default area transfer mode
- Spare area transfer mode
- Main+spare area transfer mode

The NAND flash controller determines the default transfer mode from the setting of `transfer_spare_reg` register in the `config` group. Use MAP10 commands to dynamically change the transfer mode from the existing mode to the new mode. All subsequent commands are in the new mode of transfer. You must consider that transfer modes can be changed at logical data transfer boundaries. For example:

- At the beginning or end of a page in case of single page read or write.
- At the beginning or end of a complete multi-page pipeline read or write command.

`transfer_spare_reg` and MAP10 Transfer Mode Commands

The following table lists the functionality of the MAP10 transfer mode commands, and their mappings to the `transfer_spare_reg` register in the `config` group.

Table 14-17: `transfer_spare_reg` and MAP10 Transfer Mode Commands

<code>transfer_spare_reg</code>	MAP10 Transfer Mode Commands	Resulting NAND Flash Controller Mode
0	0x42	Main ⁽⁴⁰⁾
0	0x41	Spare

⁽⁴⁰⁾ Default access mode (0x42) maps to either main (only) or main+spare mode, depending on the value of `transfer_spare_reg`.

transfer_spare_reg	MAP10 Transfer Mode Commands	Resulting NAND Flash Controller Mode
0	0x43	Main+spare
1	0x42	Main+spare ⁽⁴⁰⁾
1	0x41	Spare
1	0x43	Main+spare

Related Information

[MAP10 Commands](#) on page 14-11

Configure for Default Area Access

You only need to configure for default area access if the transfer mode was previously changed to spare area or main+spare area. To configure default area access:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any block.
2. Write 0x42 to the `Data` register.

The NAND flash controller determines the default area transfer mode from the setting of the `transfer_spare_reg` register in the `config` group. If it is set to 1, then the transfer mode becomes main+spare area, otherwise it is main area.

Configure for Spare Area Access

To access only the spare area of the flash device, use the MAP10 command to set up the NAND flash controller to read or write only the spare area on the device. After the flash controller is set up, use MAP01 read and write commands to access the spare area of the appropriate block and page addresses. To configure the NAND flash controller to access the spare area only, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the target block.
2. Write 0x41 to the `Data` register.

Configure for Main+Spare Area Access

To configure the NAND flash controller to access the main+spare area:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the target block.
2. Write 0x43 to the `Data` register.

Read-Modify-Write Operations

To read a specific page or modify a few words, bytes, or bits in a page, use the RMW operations. A read command copies the desired data from flash memory to a page buffer. You can then modify the information in the buffer using MAP00 buffer read and write commands and issue another command to write that information back to the memory.

The read-modify-write command operates on an entire page. This command is also useful for a copy type operation, where most of a page is saved to a new location. In this type of operation, the NAND flash controller reads the data, modifies a specified number of words in the page, and then writes the modified page to a new location.

Note: Because the data is modified within the page buffer of the flash device, the NAND flash controller ECC hardware is not used in RMW operations. Software must update the ECC during RMW operations.

Note: For a read-modify-write command to work with hardware ECC, the entire page must be read into system memory, modified, then written back to flash without relying on the RMW feature.

Read-Modify-Write Operation Flow

1. Start the flow by reading a page from the memory:

- Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the desired block.
- Write 0x60 to the `Data` register.

This step makes the page available to you in the page buffer in the flash device.

2. Provide the destination page address:

- Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the destination address of the desired block.
- Write 0x61 to the `Data` register.

This step initiates the page program and provides the destination address to the device.

3. Use the MAP00 page buffer read and write commands to modify the data in the page buffer.

4. Write the page buffer data back to memory:

- Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the same destination address.
- Write 0x62 to the `Data` register.

This step performs the write.

After the device completes the load operation, the NAND flash controller issues a `load_comp` interrupt. A `program_comp` interrupt is issued when the host issues the write command and the device completes the program operation.

If the page program operation (as a part of an RMW operation) results in a program failure in the device, `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copy-Back Operations

The NAND flash controller supports copy back operations. However, the flash device might have limited support for this function. If you attempt to perform a copy-back operation on a device that does not support copy-back, the NAND flash controller triggers an interrupt. An interrupt is also triggered if the source block is not specified before the destination block is specified, or if the destination block is not specified in the next command following a source block specification.

The NAND flash controller cannot do ECC validation in case of copy-back commands. The flash controller copies the ECC data, but does not check it during the copy operation.

Note: Intel recommends that you use copy-back only if the ECC implemented in the flash controller is strong enough so that the next access can correct accumulated errors.

The 8-bit value `<PP>` specifies the number of pages for copy-back. With this feature, the NAND flash controller can copy multiple consecutive pages with a single command. When you issue a copy-back

command, the flash controller performs the operation in the background. The flash controller puts other commands on hold until the current copy-back completes.

For a multi-plane device, if the `flag` bit in the `multiplane_operation` register in the `config` group is set to 1, multi-plane copy-back is available as an option. In this case, the block address specified must be plane-aligned and the value `<PP>` must specify the total number of pages to copy as a multiple of the number of planes. The block address continues incrementing, keeping the page address fixed, for the total number of planes in the device before incrementing the page address.

A `pipe_cpyback_cmd_comp` interrupt is generated when the flash controller has completed copy-back operation of all `<PP>` pages. If any page program operation (as a part of copy back operation) results in a program failure in the device, the `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copying a Memory Area (Single Plane)

To copy `<PP>` pages from one memory location to another:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied.
2. Write 0x1000 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written.
4. Write 0x11`<PP>` to the `Data` register, where `<PP>` is the number of pages to copy.

Copying a Memory Area (Multi-Plane)

To copy `<PP>` pages from one memory location to another:

1. Set the `flag` bit of the `multiplane_operation` register in the `config` group to 1.
2. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied. The address must be plane-aligned.
3. Write 0x1000 to the `Data` register.
4. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written. This address must also be plane-aligned.
5. Write 0x11`<PP>` to the `Data` register, where `<PP>` is the number of pages to copy.

The parameter `<PP>` must be a multiple of the number of planes in the device.

Pipeline Read-Ahead and Write-Ahead Operations

The NAND flash controller supports pipeline read-ahead and write-ahead operations. However, the flash device might have limited support for this function. If the device does not support pipeline read-ahead or write-ahead, the flash controller processes these commands as standard reads or writes.

The NAND flash controller can handle at the most four outstanding pipeline commands, queued up in the order in which the flash controller received the commands. The flash controller operates on the pipeline command at the head of the queue until all the pages corresponding to the pipeline command are executed. The flash controller then pops the pipeline command at the head of the queue and proceeds to work on the next pipeline command in the queue.

Pipeline Read-Ahead Function

The pipeline read-ahead function allows for a continuous reading of the flash memory. On receiving a pipeline read command, the flash controller immediately issues a load command to the device. While data

is read out with MAP01 commands in a consecutive or multi-plane address pattern, the flash controller maintains additional cache or multi-plane read command sequencing for continuous streaming of data from the flash device.

Pipeline read-ahead commands can read data from the queue in this interleaved fashion. The parameter $\langle PP \rangle$ denotes the total number of pages in multiples of the number of planes available, and the block address must be plane-aligned, which keeps the page address constant while incrementing the block address for each page-size chunk of data. After reading from every plane, the NAND flash controller increments the page address and resets the block address to the initial address. You can also use pipeline write-ahead commands in multi-plane mode. The write operation works similarly to the read operation, holding the page address constant while incrementing the block address until all planes are written.

Note: The same four-entry queue is used to queue the address and page count for pipeline read-ahead and write-ahead commands. This commonality requires that you use MAP01 commands to read out all pages for a pipeline read-ahead command before the next pipeline command can be processed. Similarly, you must write to all pages pertaining to pipeline write-ahead command before the next pipeline command can be processed.

Because the value of the `flag` bit of the `multiplane_operation` register in the `config` group determines pipeline read-ahead or write-ahead behavior, it can only be changed when the pipeline registers are empty.

When the host issues a pipeline read-ahead command, and the flash controller is idle, the load operation occurs immediately.

Note: The read-ahead command does not return the data to the host, and the write-ahead command does not write data to the flash address. The NAND flash controller loads the read data. The read data is returned to the host only when the host issues MAP01 commands to read the data. Similarly, the flash controller loads the write data, and writes it to the flash only when the host issues MAP01 commands to write the data.

Set Up a Single Area for Pipeline Read-Ahead

To set up an area for pipeline read-ahead, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-read.
2. Write $0x20\langle PP \rangle$ to the `Data` register, where the 0 sets this command as a read-ahead and $\langle PP \rangle$ is the number of pages to pre-read. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

The read-ahead command is a hint to the flash device to start loading the next page in the page buffer as soon as the previous page buffer operation has completed. After you set up the read-ahead, use a MAP01 command to actually read the data. In the MAP01 command, specify the same starting address as in the read-ahead.

If the read command received following a pipeline read-ahead request is not to a pre-read page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline read-ahead request to re-load the same data. You must use MAP01 commands to read all of the data that is pre-read before the NAND flash controller returns to the idle state.

Pipeline Write-Ahead Function

The pipeline write-ahead function allows for a continuous writing of the flash memory. While data is written with MAP01 commands in a consecutive or multi-plane address pattern, the NAND flash

controller maintains cache or multi-plane command sequences for continuous streaming of data into the flash device.

For pipeline write commands, if any page program results in a failure in the device, a `program_fail` interrupt is issued. The failing page's block and page addresses are updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Set Up a Single Area for Pipeline Write-Ahead

To set up an area for pipeline write-ahead:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-write.
2. Write `0x21<PP>` to the `Data` register, where the value 1 sets this command as a write-ahead and `<PP>` is the number of pages to pre-write. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

After you set up the write-ahead, use a `MAP01` command to write the data. In the `MAP01` command, specify the same starting address as in the write-ahead.

If the write command received following a pipeline write-ahead request is not to a pre-written page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline write-ahead request to configure the write logic.

You must use `MAP01` commands to write all of the data that is pre-written before the NAND flash controller returns to the idle state.

Other Supported Commands

`MAP01` commands must read or write pages in the same sequence that the pipelined commands were issued to the NAND flash controller. If the host issues multiple pipeline commands, pages must be read or written in the order the pipeline commands were issued. It is not possible to read or write pages for a second pipeline command before completing the first pipeline command. If the pipeline sequence is broken by a `MAP01` command, the `pipe_cmd_err` interrupt is issued, and the flash controller clears the pipeline command queue. The flash controller services the violating incoming `MAP01` read or write request with a normal page read or write sequence.

For a multi-plane device that supports multi-plane programming, you must set the `flag` bit of the `multiplane_operation` register in the `config` group to 1. In this case, the data is interleaved into page-size chunks to consecutive blocks.

A `pipe_cpyback_cmd_comp` interrupt is generated when the NAND flash controller has finished processing a pipeline command and has discarded that command from its queue. At this point of time, the host can send another pipeline command. A pipeline command is popped from the queue, and an interrupt is issued when the flash controller has started processing the last page of pipeline command. Hence, the `pipe_cpyback_cmd_comp` interrupt is issued prior to the last page load in the case of a pipeline read command and start of data transfer of the last page to be programmed, in the case of a pipeline write command.

An additional `program_comp` interrupt is generated when the last page program operation completes in the case of a pipeline write command.

If the device command set requires the NAND flash controller to issue a load command for the last page in the pipeline read command, a `load_comp` interrupt is generated after the last page load operation completes.

The pipeline commands sequence advanced commands in the device, such as cache and multi-plane. When the NAND flash controller receives a multi-page read or write pipeline command, it sequences commands sent to the device depending on settings in the following registers in the `config` group:

- `cache_read_enable`
- `cache_write_enable`
- `multiplane_operation`

For a device that supports cache read sequences, the `flag` bit of the `cache_read_enable` register must be set to 1. The NAND flash controller sequences each multi-page pipeline read command as a cache read sequence. For a device that supports cache program command sequences, `cache_write_enable` must be set. The flash controller sequences each multi-page write pipeline command as a cache write sequence.

For a device that has multi-planes and supports multi-plane program commands, the NAND flash controller register `multiplane_operation`, in the `config` group, must be set. On receiving the multi-page pipeline write command, the flash controller sequences the device with multi-plane program commands and expects that the host transfers data to the flash controller in an even-odd block increment addressing mode.

NAND Flash Controller Address Map and Register Definitions

The address map and register definitions for the NAND Flash Controller consist of the following regions:

[NAND Controller Module Data \(AXI Slave\) Address Map](#) on page 14-33

This address space is allocated for indexed addressing by the NAND flash controller.

[NAND Flash Controller Module Registers \(AXI Slave\) Address Map](#) on page 14-34

Registers in the NAND Flash Controller module accessible via its register AXI slave

Configuration registers Register Descriptions

Common across all types of flash devices, configuration registers setup the basic operating modes of the controller

Offset: 0x0

[device_reset](#) on page 14-41

Device reset. Controller sends a RESET command to device. Controller resets bit after sending command to device

[transfer_spare_reg](#) on page 14-42

Default data transfer mode. (Ignored during Spare only mode)

[load_wait_cnt](#) on page 14-43

Wait count value for Load operation

[program_wait_cnt](#) on page 14-44

Wait count value for Program operation

[erase_wait_cnt](#) on page 14-45

Wait count value for Erase operation

[int_mon_cycnt](#) on page 14-46

Interrupt monitor cycle count value

[rb_pin_enabled](#) on page 14-47

Interrupt or polling mode. Ready/Busy pin is enabled from device.

[multiplane_operation](#) on page 14-48

Multiplane transfer mode. Pipelined read, copyback, erase and program commands are transferred in multiplane mode

multiplane_read_enable on page 14-48

Device supports multiplane read command sequence

copyback_disable on page 14-49

Device does not support copyback command sequence

cache_write_enable on page 14-50

Device supports cache write command sequence

cache_read_enable on page 14-50

Device supports cache read command sequence

prefetch_mode on page 14-51

Enables read data prefetching to faster performance

chip_enable_dont_care on page 14-52

Device can work in the chip enable dont care mode

ecc_enable on page 14-53

Enable controller ECC check bit generation and correction

global_int_enable on page 14-53

Global Interrupt enable and Error/Timeout disable.

twhr2_and_we_2_re on page 14-54

tcwaw_and_addr_2_data on page 14-55

re_2_we on page 14-56

Timing parameter between re high to we low (Trhw)

acc_clks on page 14-57

Timing parameter from read enable going low to capture read data

number_of_planes on page 14-57

Number of planes in the device

pages_per_block on page 14-58

Number of pages in a block

device_width on page 14-59

I/O width of attached devices

device_main_area_size on page 14-59

Page main area size of device in bytes

device_spare_area_size on page 14-60

Page spare area size of device in bytes

two_row_addr_cycles on page 14-61

Attached device has only 2 ROW address cycles

multiplane_addr_restrict on page 14-62

Address restriction for multiplane commands

ecc_correction on page 14-62

Correction capability required

read_mode on page 14-63

The type of read sequence that the controller will follow for pipe read commands.

write_mode on page 14-66

The type of write sequence that the controller will follow for pipe write commands.

copyback_mode on page 14-67

The type of copyback sequence that the controller will follow.

rdwr_en_lo_cnt on page 14-68

Read/Write Enable low pulse width

rdwr_en_hi_cnt on page 14-69

Read/Write Enable high pulse width

max_rd_delay on page 14-70

Max round trip read data delay for data capture

cs_setup_cnt on page 14-71

Chip select setup time

spare_area_skip_bytes on page 14-71

Spare area skip bytes

spare_area_marker on page 14-72

Spare area marker value

devices_connected on page 14-73

Number of Devices connected on one bank

die_mask on page 14-74

Indicates the die differentiator in case of NAND devices with stacked dies.

first_block_of_next_plane on page 14-75

The starting block address of the next plane in a multi plane device.

write_protect on page 14-75

This register is used to control the assertion/de-assertion of the WP# pin to the device.

re_2_re on page 14-76

Timing parameter between re high to re low (Trhz) for the next bank

por_reset_count on page 14-77

The number of cycles the controller waits after reset to issue the first RESET command to the device.

watchdog_reset_count on page 14-77

The number of cycles the controller waits before flagging a watchdog timeout interrupt.

device_reset

Device reset. Controller sends a RESET command to device. Controller resets bit after sending command to device

Module Instance	Base Address	Register Address

program_wait_cnt Fields

Bit	Name	Description	Access	Reset
15:0	value	Number of clock cycles after issue of program operation before NAND Flash Controller polls for status. This values is of relevance for status polling mode of operation and has been provided to minimize redundant polling after issuing a command. After a program command, the first polling will happen after this many number of cycles have elapsed and then on polling will happen every int_mon_cycncnt cycles. The default values is equal to the default value of int_mon_cycncnt. The controller internally multiplies the value programmed into this register by 16 to provide a wider range for polling.	RW	0x1F4

erase_wait_cnt

Wait count value for Erase operation

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80040

Offset: 0x40

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0x0															

device_spare_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. The PAGE512 field of the System Manager NANDGRP_BOOTSTRAP register will determine the value of this field to be 16. Software could also choose to override the populated value.	RW	0x0

two_row_addr_cycles

Attached device has only 2 ROW address cycles

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80190

Offset: 0x190

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag
															RW 0x0

two_row_addr_cycles Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which allow for 2 ROW address cycles instead of the usual 3. Alternatively, the TWOROWADDR field of the System Manager NANDGRP_BOOTSTRAP register when asserted will set this flag.	RW	0x0

multiplane_addr_restrict

Address restriction for multiplane commands

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801A0

Offset: 0x1A0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x0

multiplane_addr_restrict Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which require that during multiplane operations all but the address for the last plane should have their address cycles tied low. The last plane address cycles has proper values. This ensures multiplane address restrictions in the device.	RW	0x0

ecc_correction

Correction capability required

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801B0

Offset: 0x1B0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x8							

ecc_correction Fields

Bit	Name	Description	Access	Reset
7:0	value	The required correction capability can be a number less than the configured error correction capability. A smaller correction capability will lead to lesser number of ECC check-bits being written per ECC sector.	RW	0x8

read_mode

The type of read sequence that the controller will follow for pipe read commands.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801C0

Offset: 0x1C0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

rdwr_en_lo_cnt

Read/Write Enable low pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801F0

Offset: 0x1F0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x12				

rdwr_en_lo_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept low to meet the min Trp/Twp parameter of the device. The value in this register plus rdwr_en_hi_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0x12

rdwr_en_hi_cnt

Read/Write Enable high pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80200

Offset: 0x200

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0xC				

rdwr_en_hi_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept high to meet the min Treh/Tweh parameter of the device. The value in this register plus rdwr_en_lo_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0xC

max_rd_delay

Max round trip read data delay for data capture

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80210

Offset: 0x210

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0x0			

max_rd_delay Fields

Bit	Name	Description	Access	Reset
3:0	value	Number of nand_mp_clk cycles after generation of feedback nand_mp_clk pulse when it is safe to synchronize received data to nand_mp_clk domain. Data should have been registered with nand_mp_clk and stable by the time max_rd_delay cycles has elapsed. A default value of zero will mean a value of nand_mp_clk multiple minus one.	RW	0x0

cs_setup_cnt

Chip select setup time

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80220

Offset: 0x220

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x3				

cs_setup_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles required for meeting chip select setup time. This register refers to device timing parameter Tcs. The value in this registers reflects the extra setup cycles for chip select before read/write enable signal is set low. The default value is calculated for ONFI Timing mode 0 Tcs = 70ns and maximum nand_mp_clk period of 4ns for 1x/4x clock multiple for 16ns cycle time device.	RW	0x3

spare_area_skip_bytes

Spare area skip bytes

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80230

Offset: 0x230

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value					
										RW 0x0					

spare_area_skip_bytes Fields

Bit	Name	Description	Access	Reset
5:0	value	Number of bytes to skip from start of spare area before last ECC sector data starts. The bytes will be written with the value programmed in the spare_area_marker register. This register could be potentially used to preserve the bad block marker in the spare area by marking it good. The default value is zero which means no bytes will be skipped and last ECC sector will start from the beginning of spare area.	RW	0x0

spare_area_marker

Spare area marker value

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80240

Offset: 0x240

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0xFFFF															

spare_area_marker Fields

Bit	Name	Description	Access	Reset
15:0	value	The value that will be written in the spare area skip bytes. This value will be used by controller while in the MAIN mode of data transfer. Only the least-significant 8 bits of the field value are used.	RW	0xFFFF

devices_connected

Number of Devices connected on one bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80250

Offset: 0x250

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													value		
													RW 0x0		

devices_connected Fields

Bit	Name	Description	Access	Reset
2:0	value	Indicates the number of devices connected to a bank. At reset, the value loaded is the maximum possible devices that could be connected in this configuration.	RW	0x0

die_mask

Indicates the die differentiator in case of NAND devices with stacked dies.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80260

Offset: 0x260

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x0							

die_mask Fields

Bit	Name	Description	Access	Reset
7:0	value	The die_mask register information will be used for devices having address restrictions. For example, in certain Samsung devices, when the first address in a two-plane command is being sent, it is expected that the address is all zeros. But if the NAND device internally has multiple dies stacked, the die information (MSB of final row address) has to be sent. The value programmed in this register will be used to mask the address while sending out the last row address.	RW	0x0

first_block_of_next_plane

The starting block address of the next plane in a multi plane device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80270

Offset: 0x270

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0x1															

first_block_of_next_plane Fields

Bit	Name	Description	Access	Reset
15:0	value	This values informs the controller of the plane structure of the device. In case the device is a multi plane device and the value here is 1, the controller understands that the next plane starts from Block number 1 and in conjunction with the number of planes parameter can decide upon the distribution of blocks in a plane in the device.	RW	0x1

write_protect

This register is used to control the assertion/de-assertion of the WP# pin to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80280

Offset: 0x280

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x1

write_protect Fields

Bit	Name	Description	Access	Reset
0	flag	When the controller is in reset, the WP# pin is always asserted to the device. Once the reset is removed, the WP# is de-asserted. The software will then have to come and program this bit to assert/de-assert the same. [list][*]1 - Write protect de-assert [*]0 - Write protect assert[/list]	RW	0x1

re_2_re

Timing parameter between re high to re low (Trhz) for the next bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80290

Offset: 0x290

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x32				

re_2_re Fields

Bit	Name	Description	Access	Reset
5:0	value	Signifies the number of bus interface nand_mp_clk clocks that should be introduced between read enable going high to a bank to the read enable going low to the next bank. The number of clocks is the function of device parameter Trhz and controller clock frequency.	RW	0x32

por_reset_count

The number of cycles the controller waits after reset to issue the first RESET command to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802A0

Offset: 0x2A0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x13B															

por_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing the first RESET command to the device. The number in this register is multiplied internally by 16 in the controller to form the final reset wait count.	RW	0x13B

watchdog_reset_count

The number of cycles the controller waits before flagging a watchdog timeout interrupt.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802B0

Offset: 0x2B0

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x5B9A															

watchdog_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing a watchdog timeout interrupt. The value in this register is multiplied internally by 32 in the controller to form the final watchdog counter.	RW	0x5B9A

Device parameters Register Descriptions

Controller reads device parameters after initialization and stores in the following registers for software

Interrupt and Status Registers Register Descriptions

Contains interrupt and status registers of controller accessible by software.

Offset: 0x400

[transfer_mode](#) on page 14-92

Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

[intr_status0](#) on page 14-93

Interrupt status register for bank 0

[intr_en0](#) on page 14-94

Enables corresponding interrupt bit in interrupt register for bank 0

[page_cnt0](#) on page 14-96

Decrementing page count bank 0

[err_page_addr0](#) on page 14-97

Erred page address bank 0

[err_block_addr0](#) on page 14-98

Erred block address bank 0

[intr_status1](#) on page 14-98

Interrupt status register for bank 1

[intr_en1](#) on page 14-100

Enables corresponding interrupt bit in interrupt register for bank 1

[page_cnt1](#) on page 14-102

Decrementing page count bank 1

[err_page_addr1](#) on page 14-102

Erred page address bank 1

[err_block_addr1](#) on page 14-103

Erred block address bank 1

[intr_status2](#) on page 14-104

Interrupt status register for bank 2

[intr_en2](#) on page 14-105

Enables corresponding interrupt bit in interrupt register for bank 2

[page_cnt2](#) on page 14-107

Decrementing page count bank 2

[err_page_addr2](#) on page 14-108

Erred page address bank 2

[err_block_addr2](#) on page 14-108

Erred block address bank 2

[intr_status3](#) on page 14-109

Interrupt status register for bank 3

[intr_en3](#) on page 14-111

Enables corresponding interrupt bit in interrupt register for bank 3

[page_cnt3](#) on page 14-112

Decrementing page count bank 3

[err_page_addr3](#) on page 14-113

Erred page address bank 3

[err_block_addr3](#) on page 14-114

Erred block address bank 3

transfer_mode

Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

The hard processor system (HPS) provides a Secure Digital/Multimedia Card (SD/MMC) controller for interfacing to external SD and MMC flash cards, secure digital I/O (SDIO) devices, and Consumer Electronics Advanced Transport Architecture (CE-ATA) hard drives. The SD/MMC controller enables you to store boot images and boot the processor system from the removable flash card. You can also use the flash card to expand the on-board storage capacity for larger applications or user data. Other applications include interfacing to embedded SD (eSD) and embedded MMC (eMMC) non-removable flash devices.

The SD/MMC controller is based on the Synopsys DesignWare Mobile Storage Host (SD/MMC controller) controller.

This document refers to SD/SDIO commands, which are documented in detail in the *Physical Layer Simplified Specification, Version 3.01* and the *SDIO Simplified Specification, Version 2.00* described on the SD Association website.

Related Information

Features of the SD/MMC Controller

The HPS SD/MMC controller offers the following features:

- Supports HPS boot from mobile storage
- Supports the following standards or card types:⁽⁴¹⁾
 - SD, including eSD—version 3.0
 - SDIO, including embedded SDIO (eSDIO)—version 3.0
 - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41⁽⁴²⁾
 - MMC: 1-bit data bus
 - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
 - MMCPlus: 1-bit, 4-bit, and optional 8-bit data bus
 - MMCMobile: 1-bit data bus
 - Embedded MMC (eMMC): 1-bit, 4-bit, and 8-bit data bus
- Integrated descriptor-based direct memory access (DMA)
- Internal 4 KB receive and transmit FIFO buffer

Unsupported Features

- Card Detect is only supported on interfaces routed via the FPGA fabric. The Card Detect Interface signals are not included if the interface is pinned out to HPS I/O.
- The SD/MMC controller does not directly support voltage switching, card interrupts, or back-end power control of eSDIO card devices. However, you can connect these signals to general-purpose I/Os (GPIOs).
- The SD/MMC controller does not contain a reset output as part of the external card interface. To reset the flash card device, consider using a general purpose output pin.

Related Information

- [MMC Support Matrix](#) on page 15-3
For more information on what is supported, refer to the MMC Support Matrix table.

For more information, refer to the supported SD/SDHC/SDXC/MMC/eMMC flash devices section on this page.

SD Card Support Matrix

Table 15-1: SD Card Support Matrix

Device Card Type	Voltages Supported ⁽⁴³⁾		Bus Modes Supported			Bus Speed Modes Supported			
	3.0 V	1.8 V ⁽⁴⁵⁾	1 bit	4 bit	8 bit	Default Speed	High Speed	SDR12	SDR25 ⁽⁴⁴⁾
						12.5 MBps 25 MHz	25 MBps 50 MHz	12.5 MBps 25 MHz	25 MBps 50 MHz
SDSC (SD)	√		√			√	√		
SDHC	√	√	√	√		√	√	√	√
SDXC	√	√	√	√		√	√	√	√
eSD	√	√	√	√		√	√	√	√
SDIO	√	√	√	√		√	√	√	√
eSDIO	√	√	√	√	√	√	√	√	√

Note: Card form factors (such as mini and micro) are not enumerated in the above table because they do not impact the card interface functionality.

⁽⁴¹⁾ SD and SDIO do not support SDR50, SDR104, and DDR50 modes.

⁽⁴²⁾ DDR timing is optional for MMCPlus, MMCMobile, and eMMC; but not supported for MMC and RSMCMC.

⁽⁴³⁾ Because SD cards initially operate at 3.0 V and can switch to 1.8V after power-up and the BSEL values are constant during the boot process, transceivers are required to support level-shifting and isolation.

⁽⁴⁴⁾ SDR25 speed mode requires 1.8-V signaling. Note that even if a card supports UHS-I modes (for example SDR50, SDR104, DDR50) it can still communicate at the lower speeds (for example SDR12, SDR25).

⁽⁴⁵⁾ Where supported, external transceivers are needed to switch the voltage.

MMC Support Matrix

Table 15-2: MMC Support Matrix

Card Device Type	Max Clock Speed (MHz)	Max Data Rate (MBps)	Voltages Supported		Bus Modes Supported			Bus Speed Modes Supported	
			3.3 V	1.8 V	1 bit	4 bit	8 bit	Default Speed	High Speed
MMC	20	2.5	√		√			√	
RSDMMC	20	10	√		√	√		√	√
MMCPlus	50 ⁽⁴⁶⁾	25	√		√	√	√ ⁽⁴⁷⁾	√	√
MMCMobile	50	6.5	√	√	√			√	√
eMMC	50	25	√	√	√	√	√	√	√

SD/MMC Controller Block Diagram and System Integration

The SD/MMC controller includes a bus interface unit (BIU) and a card interface unit (CIU). The BIU provides a slave interface for a host to access the control and status registers (CSRs). Additionally, this unit also provides independent FIFO buffer access through a DMA interface. The DMA controller is responsible for exchanging data between the system memory and FIFO buffer. The DMA registers are accessible by the host to control the DMA operation. The CIU supports the SD, MMC, and CE-ATA protocols on the controller, and provides clock management through the clock control block. The interrupt control block for generating an interrupt connects to the generic interrupt controller in the Arm Cortex-A9 microprocessor unit (MPU) subsystem.

⁽⁴⁶⁾ Supports a maximum clock rate of 50 MHz instead of 52 MHz (specified in MMC specification).

⁽⁴⁷⁾ Optional 8-bit bus mode not supported in all packages.

Figure 15-1: SD/MMC Controller Connectivity

SD/MMC Controller Signal Description

The following table shows the SD/MMC controller signals that are routed to the FPGA and the HPS I/O.

Note: The last five signals in the table are not routed to HPS I/O, but only to the FPGA.

Table 15-3: SD/MMC Controller Interface I/O Pins

Signal	Width	Direction	Description
sdmmc_cclk_out	1	Out	Clock from controller to the card
sdmmc_cmd_i	1	In	Card command
sdmmc_cmd_o	1	Out	
sdmmc_cmd_oe		Out	
sdmmc_pwr_ena_o	1	Out	

Signal	Width	Direction	Description
sdmmc_data_i	8	In	Card data
sdmmc_data_o	8	Out	
sdmmc_data_oe	1	Out	
sdmmc_cdn_i	1	In	Card detect signal
sdmmc_wp_i	1	In	Card write protect signal
sdmmc_vs_o	1	Out	Voltage switching between 3.3V and 1.8V
sdmmc_rstn_o	1	Out	Card reset signal used in MMC mode
sdmmc_card_intn_i	1	In	Card interrupt signal

Functional Description of the SD/MMC Controller

This section describes the SD/MMC controller components and how the controller operates.

SD/MMC/CE-ATA Protocol

The SD/MMC/CE-ATA protocol is based on command and data bit streams that are initiated by a start bit and terminated by a stop bit. Additionally, the SD/MMC controller provides a reference clock and is the only master interface that can initiate a transaction.[†]

- Command—a token transmitted serially on the `CMD` pin that starts an operation.[†]
- Response—a token from the card transmitted serially on the `CMD` pin in response to certain commands.[†]
- Data—transferred serially using the data pins for data movement commands.[†]

In the following figure, the clock is a representative only and does not show the exact number of clock cycles.

Figure 15-2: Multiple-Block Read Operation[†]

The following figure illustrates an example of a command token sent by the host in a multiple-block write operation.

Figure 15-3: Multiple-Block Write Operation[†]

BIU

The Bus Interface Unit (BIU) interfaces with the Card Interface Unit (CIU), and is connected to the level 3 (L3) interconnect and level 4 (L4) peripheral buses. The BIU consists of the following primary functional blocks, which are defined in the following sections:

- Slave interface
- Register block
- FIFO buffer
- Interrupt control
- Internal DMA controller

Slave Interface

The host processor accesses the SD/MMC controller registers and data FIFO buffers through the slave interface.

Register Block

The register block is part of the BIU and provides read and write access to the CSRs.

All registers reside in the BIU clock domain, `l4_mp_clk`. When a command is sent to a card by setting the start command bit (`start_cmd`) of the command register (`cmd`) to 1, all relevant registers needed for the CIU operation are copied to the CIU block. During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to reset the `start_cmd` bit to 0 before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.

Registers Locked Out Pending Command Acceptance

After a command start is issued by setting the `start_cmd` bit of the `cmd` register, the following registers cannot be rewritten until the command is accepted by the CIU:[†]

- Command (`cmd`)[†]
- Command argument (`cmdarg`)[†]
- Byte count (`bytcnt`)[†]
- Block size (`blksiz`)[†]
- Clock divider (`clkdiv`)[†]
- Clock enable (`ckena`)[†]
- Clock source (`clksrc`)[†]
- Timeout (`tmout`)[†]
- Card type (`ctype`)[†]

The hardware resets the `start_cmd` bit after the CIU accepts the command. If a host write to any of these registers is attempted during this locked time, the write is ignored and the hardware lock write error bit (`hle`) is set to 1 in the raw interrupt status register (`rintsts`). Additionally, if the interrupt is enabled and not masked for a hardware lock error, an interrupt is sent to the host.[†]

Once a command is accepted, you can send another command to the CIU—which has a one-deep command queue—under the following conditions:[†]

- If the previous command is not a data transfer command, the new command is sent to the SD/MMC/CE-ATA card once the previous command completes.[†]
- If the previous command is a data transfer command and if the wait previous data complete bit (`wait_prvdata_complete`) of the `cmd` register is set to 1 for the new command, the new command is sent to the SD/MMC/CE-ATA card only when the data transfer completes.[†]
- If the `wait_prvdata_complete` bit is 0, the new command is sent to the SD/MMC/CE-ATA card as soon as the previous command is sent. Typically, use this feature to stop or abort a previous data transfer or query the card status in the middle of a data transfer.[†]

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the `rintsts` register, the interrupt mask register (`intmask`), and the interrupt enable bit (`int_enable`) of the control register (`ctrl`). Once an interrupt condition is detected, the controller sets the corresponding interrupt bit in the `rintsts` register. The bit in the `rintsts` register remains set until the software clears the bit by writing a 1 to the interrupt bit; writing a 0 leaves the bit untouched.

The interrupt controller unit generates active high, level sensitive interrupts that are asserted only when at least one bit in the `rintsts` register is set to 1, the corresponding `intmask` register bit is 1, and the `int_enable` bit of the `ctrl` register is 1.

The `int_enable` bit of the `ctrl` register is cleared during a power-on reset, and the `intmask` register bits are set to 0x0000000, which masks all the interrupts.

Table 15-4: Interrupt Status Register Bits[†]

Bits	Interrupt	Description
16	SDIO Interrupts [†]	Interrupts from SDIO cards. [†]
15	End Bit Error (read)/Write no CRC (EBE) [†]	Error in end-bit during read operation, or no data CRC received during write operation. [†] Note: For MMC CMD19, there may be no CRC status returned by the card. Hence, EBE is set for CMD19. The application should not treat this as an error. [†]
14	Auto Command Done (ACD) [†]	Stop/abort commands automatically sent by card unit and not initiated by host; similar to Command Done (CD) interrupt. [†] Recommendation: Software typically need not enable this for non CE-ATA accesses; Data Transfer Over (DTO) interrupt that comes after this interrupt determines whether data transfer has correctly completed. For CE-ATA accesses, if the software sets <code>send_auto_stop_ccsd</code> bit in the control register, then software should enable this bit. [†]
13	Start Bit Error (SBE)	Error in data start bit when data is read from a card. In 4-bit mode, if all data bits do not have start bit, then this error is set.
12	Hardware Locked write Error (HLE) [†]	During hardware-lock period, write attempted to one of locked registers. [†]

Bits	Interrupt	Description
11	FIFO Underrun/Overrun Error (FRUN) [†]	<p>Host tried to push data when FIFO was full, or host tried to read data when FIFO was empty. Typically this should not happen, except due to error in software. [†]</p> <p>Card unit never pushes data into FIFO when FIFO is full, and pop data when FIFO is empty. [†]</p> <p>If IDMAC (Internal Direct Memory Access Controller) is enabled, FIFO underrun/overrun can occur due to a programming error on MSIZE and watermark values in FIFOTH register; for more information, refer to <i>Internal Direct Memory Access Controller (IDMAC)</i> section in the "Synopsys DesignWare Cores Mobile Storage Host Databook".[†]</p>
10	Data Starvation by Host Timeout (HTO) [†]	<p>To avoid data loss, card clock out (<code>cclk_out</code>) is stopped if FIFO is empty when writing to card, or FIFO is full when reading from card. Whenever card clock is stopped to avoid data loss, data-starvation timeout counter is started with data-timeout value. This interrupt is set if host does not fill data into FIFO during write to card, or does not read from FIFO during read from card before timeout period. [†]</p> <p>Even after timeout, card clock stays in stopped state, with CIU state machines waiting. It is responsibility of host to push or pop data into FIFO upon interrupt, which automatically restarts <code>cclk_out</code> and card state machines. [†]</p> <p>Even if host wants to send stop/abort command, it still must ensure to push or pop FIFO so that clock starts in order for stop/abort command to send on <code>cmd</code> signal along with data that is sent or received on data line. [†]</p>

Bits	Interrupt	Description
9	Data Read Timeout (DRTO)/Boot Data Start (BDS) [†]	<ul style="list-style-type: none"> In Normal functioning mode: Data read timeout (DRTO) Data timeout occurred. Data Transfer Over (DTO) also set if data timeout occurs. [†] In Boot Mode: Boot Data Start (BDS) When set, indicates that SD/MMC controller has started to receive boot data from the card. A write to this register with a value of 1 clears this interrupt. [†]
8	Response Timeout (RTO)/ Boot Ack Received (BAR) [†]	<ul style="list-style-type: none"> In Normal functioning mode: Response timeout (RTO) Response timeout occurred. Command Done (CD) also set if response timeout occurs. If command involves data transfer and when response times out, no data transfer is attempted by SD/MMC controller. [†] In Boot Mode: Boot Ack Received (BAR) When expect_boot_ack is set, on reception of a boot acknowledge pattern—0-1-0—this interrupt is asserted. A write to this register with a value of 1 clears this interrupt. [†]
7	Data CRC Error (DCRC) [†]	Received Data CRC does not match with locally-generated CRC in CIU; expected when a negative CRC is received. [†]
6	Response CRC Error (RCRC) [†]	Response CRC does not match with locally-generated CRC in CIU. [†]
5	Receive FIFO Data Request (RXDR) [†]	<p>Interrupt set during read operation from card when FIFO level is greater than Receive-Threshold level. [†]</p> <p>Recommendation: In DMA modes, this interrupt should not be enabled. [†]</p> <p>ISR, in non-DMA mode:</p> <pre>pop RX_WMark + 1 data from FIFO</pre> <p>[†]</p>

Bits	Interrupt	Description
4	Transmit FIFO Data Request (TXDR) [†]	<p>Interrupt set during write operation to card when FIFO level reaches less than or equal to Transmit-Threshold level.[†]</p> <p>Recommendation: In DMA modes, this interrupt should not be enabled.[†]</p> <p>ISR in non-DMA mode: [†]</p> <pre> if (pending_bytes > \ (FIFO_DEPTH - TX_WMark))[†] push (FIFO_DEPTH - \ TX_WMark) data into FIFO[†] else[†] push pending_bytes data \ into FIFO[†] </pre>
3	Data Transfer (DTO) [†]	<p>Data transfer completed, even if there is Start Bit Error or CRC error. This bit is also set when “read data-timeout” occurs or CCS is sampled from CE-ATA device.[†]</p> <p>Recommendation: In non-DMA mode, when data is read from card, on seeing interrupt, host should read any pending data from FIFO. In DMA mode, DMA controllers guarantee FIFO is flushed before interrupt.[†]</p> <p>Note: DTO bit is set at the end of the last data block, even if the device asserts MMC busy after the last data block.[†]</p>
2	Command Done (CD) [†]	<p>Command sent to card and received response from card, even if Response Error or CRC error occurs. Also set when response timeout occurs or CCSD sent to CE-ATA device.[†]</p>
1	Response Error (RE) [†]	<p>Error in received response set if one of following occurs:[†]</p> <ul style="list-style-type: none"> • Transmission bit != 0[†] • Command index mismatch[†] • End-bit != 1[†]

Bits	Interrupt	Description
0	Card-Detect (CDT) [†]	<p>When one or more cards inserted or removed, this interrupt occurs. Software should read card-detect register (CDETECT, 0x50) to determine current card status.[†]</p> <p>Recommendation: After power-on and before enabling interrupts, software should read card detect register and store it in memory. When interrupt occurs, it should read card detect register and compare it with value stored in memory to determine which card(s) were removed/inserted. Before exiting ISR, software should update memory with new card-detect value.[†]</p>

Interrupt Setting and Clearing

The SDIO Interrupts, Receive FIFO Data Request, and Transmit FIFO Data Request interrupts are set by level-sensitive interrupt sources. Therefore, the interrupt source must be first cleared before you can reset the interrupt's corresponding bit in the `rintsts` register to 0.[†]

For example, on receiving the Receive FIFO Data Request interrupt, the FIFO buffer must be emptied so that the FIFO buffer count is not greater than the RX watermark, which causes the interrupt to be triggered.[†]

The rest of the interrupts are triggered by single clock-pulse-width sources.[†]

FIFO Buffer

The SD/MMC controller has a 4 KB data FIFO buffer for storing transmit and receive data. The FIFO buffer memory supports error correction codes (ECCs). Both interfaces to the FIFO buffer support single and double bit error injection. The enable and error injection pins are inputs driven by the system manager and the status pins are outputs driven to the MPU subsystem.

The SD/MMC controller provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

Note: Initialization of memory data before enabling ECC prevents spurious ECC interrupts when you enable ECC for the first time.

Internal DMA Controller

Internal DMA controller (AHB Master) enables the core to act as a Master on the AHB to transfer data to and from the AHB.

- Supports 32-bit data
- Supports split, retry, and error AHB responses, but does not support wrap
- Configurable for little-endian or big-endian mode
- Allows the selection of AHB burst type through software

The internal DMA controller has a CSR and a single transmit or receive engine, which transfers data from system memory to the card and vice versa. The controller uses a descriptor mechanism to efficiently move data from source to destination with minimal host processor intervention. You can configure the controller to interrupt the host processor in situations such as transmit and receive data transfer completion from the card, as well as other normal or error conditions. The DMA controller and the host driver communicate through a single data structure.[†]

The internal DMA controller transfers the data received from the card to the data buffer in the system memory, and transfers transmit data from the data buffer in the memory to the controller’s FIFO buffer. Descriptors that reside in the system memory act as pointers to these buffers.[†]

A data buffer resides in the physical memory space of the system memory and consists of complete or partial data. The buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data buffers.[†]

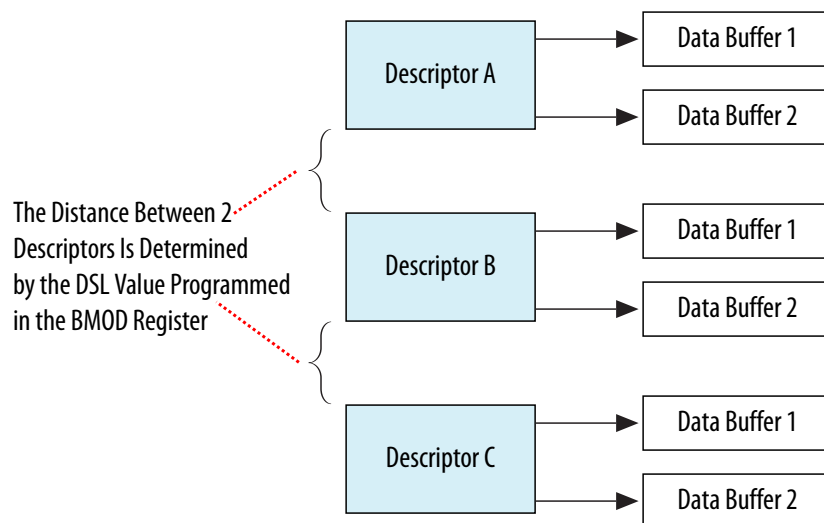

A single descriptor is used for both reception and transmission. The base address of the list is written into the descriptor list base address register (*dbaddr*). A descriptor list is forward linked. The last descriptor can point back to the first entry to create a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.[†]

Internal DMA Controller Descriptors

The internal DMA controller uses these types of descriptor structures:[†]

- Dual-buffer structure—The distance between two descriptors is determined by the skip length value written to the descriptor skip length field (*dsl*) of the bus mode register (*bmod*).[†]

Figure 15-4: Dual-Buffer Descriptor Structure[†]

- Chain structure—Each descriptor points to a unique buffer, and to the next descriptor in a linked list.[†]

Figure 15-5: Chain Descriptor Structure[†]

Internal DMA Controller Descriptor Address

The descriptor address must be aligned to the 32-bit bus. Each descriptor contains 16 bytes of control and status information.[†]

Table 15-5: Descriptor Format

Name	Off-set	31	30	29:27	26	25:14	13	12:7	6	5	4	3	2	1	0
DES0	0	OWN	CES	—						ER	CH	FS	LD	DIC	—
DES1	4	—				BS2		BS1							
DES2	8	BAP1													
DES3	12	BAP2 or Next Descriptor Address													

Related Information

[Internal DMA Controller Descriptor Fields](#) on page 15-14

Refer to this table for information about each of the bits of the descriptor.

Internal DMA Controller Descriptor Fields

The DES0 field in the internal DMA controller descriptor contains control and status information.

Table 15-6: Internal DMA Controller DES0 Descriptor Field[†]

Bits	Name	Description
31	OWN	<p>When set to 1, this bit indicates that the descriptor is owned by the internal DMA controller.</p> <p>When this bit is set to 0, it indicates that the descriptor is owned by the host. The internal DMA controller resets this bit to 0 when it completes the data transfer.</p>
30	Card Error Summary (CES)	<p>The CES bit indicates whether a transaction error occurred. The CES bit is the logical OR of the following error bits in the <code>rintsts</code> register.</p> <ul style="list-style-type: none"> • End-bit error (<code>ebe</code>) • Response timeout (<code>rto</code>) • Response CRC (<code>rcrc</code>) • Start-bit error (<code>sbe</code>) • Data read timeout (<code>drtto</code>) • Data CRC for receive (<code>dcrc</code>) • Response error (<code>re</code>)
29:6	Reserved	—
5	End of Ring (ER)	<p>When set to 1, this bit indicates that the descriptor list reached its final descriptor. The internal DMA controller returns to the base address of the list, creating a descriptor ring. ER is meaningful for only a dual-buffer descriptor structure.</p>
4	Second Address Chained (CH)	<p>When set to 1, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set to 1, BS2 (DES1[25:13]) must be all zeros.</p>
3	First Descriptor (FD)	<p>When set to 1, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.</p>
2	Last Descriptor (LD)	<p>When set to 1, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the data.</p>
1	Disable Interrupt on Completion (DIC)	<p>When set to 1, this bit prevents the setting of the TI/RI bit of the internal DMA controller status register (<code>idsts</code>) for the data that ends in the buffer pointed to by this descriptor.</p>
0	Reserved	—

Table 15-7: Internal DMA Controller DES1 Descriptor Field[†]

The DES1 descriptor field contains the buffer size.

Bits	Name	Description
31:26	Reserved	—
25:13	Buffer 2 Size (BS2)	This field indicates the second data buffer byte size. The buffer size must be a multiple of four. When the buffer size is not a multiple of four, the resulting behavior is undefined. This field is not valid if DES0[4] is set to 1.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of four bytes. When the buffer size is not a multiple of four, the resulting behavior is undefined. If this field is 0, the DMA ignores the buffer and proceeds to the next descriptor for a chain structure, or to the next buffer for a dual-buffer structure. If there is only one descriptor and only one buffer to be programmed, you need to use only buffer 1 and not buffer 2.

Table 15-8: Internal DMA Controller DES2 Descriptor Field[†]

The DES2 descriptor field contains the address pointer to the data buffer.

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The internal DMA controller ignores DES2 [1:0], because it only performs 32-bit aligned accesses.

Table 15-9: Internal DMA Controller DES3 Descriptor Field[†]

The DES3 descriptor field contains the address pointer to the next descriptor if the present descriptor is not the last descriptor in a chained descriptor structure or the second buffer address for a dual-buffer structure.[†]

Bits	Name	Description
31:0	Buffer Address Pointer 2 (BAP2) or Next Descriptor Address	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set to 1, this address contains the pointer to the physical memory where the next descriptor is present. If this is not the last descriptor, the next descriptor address pointer must be aligned to 32 bits. Bits 1 and 0 are ignored.

Host Bus Burst Access

The internal DMA controller attempts to issue fixed-length burst transfers on the master interface if configured using the fixed burst bit (fb) of the bmod register. The maximum burst length is indicated and limited by the programmable burst length (pbl) field of the bmod register. When descriptors are being fetched, the master interface always presents a burst size of four to the interconnect.[†]

The internal DMA controller initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO buffer or the number of bytes to the end of transfer is less than the configured burst-length. When the DMA master interface is configured for fixed-length bursts, it transfers data using the most efficient combination of INCR4, INCR8 or INCR16 and SINGLE transactions. If the DMA master interface is not configured for fixed length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.[†]

Host Data Buffer Alignment

The transmit and receive data buffers in system memory must be aligned to a 32-bit boundary.

Buffer Size Calculations

The driver knows the amount of data to transmit or receive. For transmitting to the card, the internal DMA controller transfers the exact number of bytes from the FIFO buffer, indicated by the buffer size field of the DES1 descriptor field.[†]

If a descriptor is not marked as last (with the LD bit of the DES0 field set to 0) then the corresponding buffer(s) of the descriptor are considered full, and the amount of valid data in a buffer is accurately indicated by its buffer size field. If a descriptor is marked as last, the buffer might or might not be full, as indicated by the buffer size in the DES1 field. The driver is aware of the number of locations that are valid.[†] The driver is expected to ignore the remaining, invalid bytes.

Internal DMA Controller Interrupts

Interrupts can be generated as a result of various events. The idsts register contains all the bits that might cause an interrupt. The internal DMA controller interrupt enable register (idinten) contains an enable bit for each of the events that can cause an interrupt to occur.[†]

There are two summary interrupts—the normal interrupt summary bit (nis) and the abnormal interrupt summary bit (ais)—in the idsts register.[†] The nis bit results from a logical OR of the transmit interrupt (ti) and receive interrupt (ri) bits in the idsts register. The ais bit is a logical OR result of the fatal bus error interrupt (fbe), descriptor unavailable interrupt (du), and card error summary interrupt (ces) bits in the idsts register.

Interrupts are cleared by writing a 1 to the corresponding bit position.[†] If a 0 is written to an interrupt's bit position, the write is ignored, and does not clear the interrupt. When all the enabled interrupts within a group are cleared, the corresponding summary bit is set to 0. When both the summary bits are set to 0, the interrupt signal is de-asserted.[†]

Interrupts are not queued. If another interrupt event occurs before the driver has responded to the previous interrupt, no additional interrupts are generated. For example, the ri bit of the idsts register indicates that one or more data has been transferred to the host buffer.[†]

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the idsts register for the interrupt cause.[†] The final interrupt signal from the controller is a logical OR of the interrupts from the BIU and internal DMA controller.

Internal DMA Controller Functional State Machine[†]

The following list explains each state of the functional state machine:[†]

1. The internal DMA controller performs four accesses to fetch a descriptor.[†]
2. The DMA controller stores the descriptor information internally. If it is the first descriptor, the controller issues a FIFO buffer reset and waits until the reset is complete.[†]
3. The internal DMA controller checks each bit of the descriptor for the correctness. If bit mismatches are found, the appropriate error bit is set to 1 and the descriptor is closed by setting the OWN bit in the DES0 field to 1.[†]

The `rintsts` register indicates one of the following conditions:[†]

- Response timeout[†]
 - Response CRC error[†]
 - Data receive timeout[†]
 - Response error[†]
4. The DMA waits for the RX watermark to be reached before writing data to system memory, or the TX watermark to be reached before reading data from system memory. The RX watermark represents the number of bytes to be locally stored in the FIFO buffer before the DMA writes to memory. The TX watermark represents the number of free bytes in the local FIFO buffer before the DMA reads data from memory.[†]
 5. If the value of the programmable burst length (PBL) field is larger than the remaining amount of data in the buffer, single transfers are initiated. If dual buffers are being used, and the second buffer contains no data (buffer size = 0), the buffer is skipped and the descriptor is closed.[†]
 6. The OWN bit in descriptor is set to 0 by the internal DMA controller after the data transfer for one descriptor is completed. If the transfer spans more than one descriptor, the DMA controller fetches the next descriptor. If the transfer ends with the current descriptor, the internal DMA controller goes to idle state after setting the `ri` bit or the `ti` bit of the `idsts` register. Depending on the descriptor structure (dual buffer or chained), the appropriate starting address of descriptor is loaded. If it is the second data buffer of dual buffer descriptor, the descriptor is not fetched again.[†]

Abort During Internal DMA Transfer

If the host issues an SD/SDIO STOP_TRANSMISSION command (CMD12) to the card while data transfer is in progress, the internal DMA controller closes the present descriptor after completing the data transfer until a Data Transfer Over (DTO) interrupt is asserted. Once a STOP_TRANSMISSION command is issued, the DMA controller performs single burst transfers.[†]

- For a card write operation, the internal DMA controller keeps writing data to the FIFO buffer after fetching it from the system memory until a DTO interrupt is asserted. This is done to keep the card clock running so that the STOP_TRANSMISSION command is reliably sent to the card.[†]
- For a card read operation, the internal DMA controller keeps reading data from the FIFO buffer and writes to the system memory until a DTO interrupt is generated. This is required because DTO interrupt is not generated until and unless all the FIFO buffer data is emptied.[†]

Note: For a card write abort, only the current descriptor during which a STOP_TRANSMISSION command is issued is closed by the internal DMA controller. The remaining unread descriptors are not closed by the internal DMA controller.[†]

Note: For a card read abort, the internal DMA controller reads the data out of the FIFO buffer and writes them to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.[†]

Fatal Bus Error Scenarios

A fatal bus error occurs when the master interface issues an error response. This error is a system error, so the software driver must not perform any further setup on the controller. The only recovery mechanism from such scenarios is to perform one of the following tasks:[†]

- Issue a reset to the controller through the reset manager.[†]
- Issue a program controller reset by writing to the controller reset bit (`controller_reset`) of the `ctrl` register.[†]

FIFO Buffer Overflow and Underflow

During normal data transfer conditions, FIFO buffer overflow and underflow does not occur. However, if there is a programming error, a FIFO buffer overflow or underflow can result. For example, consider the following scenarios.[†]

For transmit:[†]

- PBL=4[†]
- TX watermark = 1[†]

For these programming values, if the FIFO buffer has only one location empty, the DMA attempts to read four words from memory even though there is only one word of storage available. This results in a FIFO Buffer Overflow interrupt.[†]

For receive:[†]

- PBL=4[†]
- RX watermark = 1[†]

For these programming values, if the FIFO buffer has only one location filled, the DMA attempts to write four words, even though only one word is available. This results in a FIFO Buffer Underflow interrupt.[†]

The driver must ensure that the number of bytes to be transferred, as indicated in the descriptor, is a multiple of four bytes. For example, if the `bytCnt` register = 13, the number of bytes indicated in the descriptor must be rounded up to 16 because the length field must always be a multiple of four bytes.[†]

PBL and Watermark Levels

This table shows legal PBL and FIFO buffer watermark values for internal DMA controller data transfer operations.[†]

Table 15-10: PBL and Watermark Levels[†]

PBL (Number of transfers)	TX/RX FIFO Buffer Watermark Value
1	greater than or equal to 1
4	greater than or equal to 4
8	greater than or equal to 8
16	greater than or equal to 16
32	greater than or equal to 32
64	greater than or equal to 64
128	greater than or equal to 128
256	greater than or equal to 256

CIU

The Card Interface Unit (CIU) interfaces with the BIU and SD/MMC cards or devices. The host processor writes command parameters to the SD/MMC controller's BIU control registers and these parameters are then passed to the CIU. Depending on control register values, the CIU generates SD/MMC command and data traffic on the card bus according to the SD/MMC protocol. The control register values also decide whether the command and data traffic is directed to the CE-ATA card, and the SD/MMC controller controls the command and data path accordingly.[†]

The following list describes the CIU operation restrictions:[†]

- After a command is issued, the CIU accepts another command only to check read status or to stop the transfer.[†]
- Only one data transfer command can be issued at a time.[†]
- During an open-ended card write operation, if the card clock is stopped because the FIFO buffer is empty, the software must first fill the data into the FIFO buffer and start the card clock. It can then issue only an SD/SDIO STOP_TRANSMISSION (CMD12) command to the card.[†]
- During an SDIO/COMBO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO buffer and start the resume command as if it were a new data transfer command.[†]
- When issuing SD/SDIO card reset commands (GO_IDLE_STATE, GO_INACTIVE_STATE or CMD52_reset) while a card data transfer is in progress, the software must set the stop abort command bit (`stop_abort_cmd`) in the `cmd` register to 1 so that the controller can stop the data transfer after issuing the card reset command.[†]
- If the card clock is stopped because the FIFO buffer is full during a card read, the software must read at least two FIFO buffer locations to start the card clock.[†]
- If CE-ATA card device interrupts are enabled (the `nIEN` bit is set to 0 in the ATA control register), a new RW_BLK command must not be sent to the same card device if there is a pending RW_BLK command in progress (the RW_BLK command used in this document is the RW_MULTIPLE_BLOCK MMC command defined by the CE-ATA specification). Only the Command Completion Signal Disable (CCSD) command can be sent while waiting for the Command Completion Signal (CCS).[†]
- For the same card device, a new command is allowed for reading status information, if interrupts are disabled in the CE-ATA card (the `nIEN` bit is set to 1 in the ATA control register).[†]
- Open-ended transfers are not supported for the CE-ATA card devices.[†]
- The `send_auto_stop` signal is not supported (software must not set the `send_auto_stop` bit in the `cmd` register) for CE-ATA transfers.[†]

The CIU consists of the following primary functional blocks:[†]

- Command path[†]
- Data path[†]
- Clock control[†]

Command Path

The command path performs the following functions:[†]

- Load card command parameters[†]
- Send commands to card bus[†]
- Receive responses from card bus[†]
- Send responses to BIU[†]
- Load clock parameters[†]
- Drives the P-bit on command pin[†]

A new command is issued to the controller by writing to the BIU registers and setting the `start_cmd` bit in the `cmd` register. The command path loads the new command (command, command argument, timeout) and sends an acknowledgement to the BIU.[†]

After the new command is loaded, the command path state machine sends a command to the card bus—including the internally generated seven-term CRC (CRC-7)—and receives a response, if any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command. In CE-ATA data payload transfer (RW_MULTIPLE_BLOCK) commands, if the card device interrupts are enabled (the `nIEN` bit is set to 0

in the ATA control register), the state machine performs the following actions after receiving the response:[†]

- Does not drive the P-bit; it waits for CCS, decodes and goes back to idle state, and then drives the P-bit.[†]
- If the host wants to send the CCSD command and if eight clock cycles are expired after the response, it sends the CCSD pattern on the command pin.[†]

Load Command Parameters

Commands or responses are loaded in the command path in the following situations:[†]

- New command from BIU—When the BIU sends a new command to the CIU, the `start_cmd` bit is set to 1 in the `cmd` register.[†]
- Internally-generated `send_auto_stop`—When the data path ends, the SD/SDIO STOP command request is loaded.[†]
- Interrupt request (IRQ) response with relative card address (RCA) 0x000—When the command path is waiting for an IRQ response from the MMC and a “send irq response” request is signaled by the BIU, the send IRQ request bit (`send_irq_response`) is set to 1 in the `ctrl` register.[†]

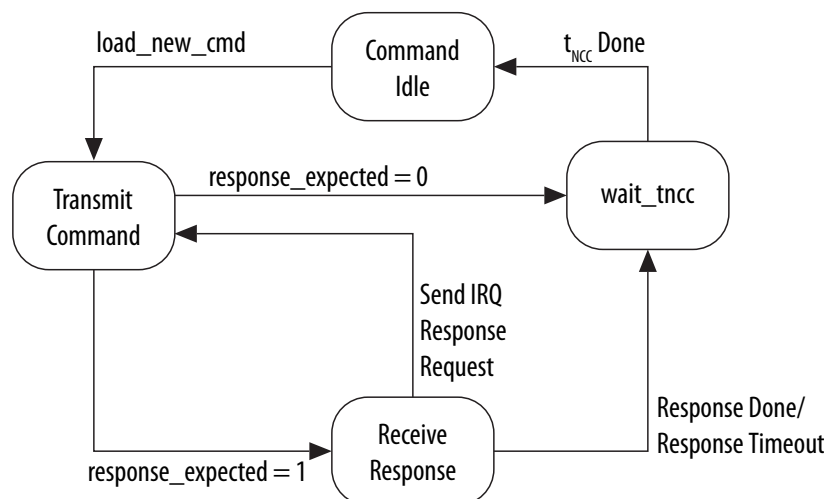

Loading a new command from the BIU in the command path depends on the following `cmd` register bit settings:[†]

- `update_clock_registers_only`—If this bit is set to 1 in the `cmd` register, the command path updates only the `clkena`, `clkdiv`, and `clksrc` registers. If this bit is set to 0, the command path loads the `cmd`, `cmdarg`, and `tmout` registers. It then processes the new command, which is sent to the card.[†]
- `wait_prvdata_complete`—If this bit is set to 1, the command path loads the new command under one of the following conditions:[†]
 - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (`bytcnt = 0`).[†]
 - After completion of the current data transfer, if a predefined data transfer is in progress.[†]

Send Command and Receive Response

After a new command is loaded in the command path (the `update_clock_registers_only` bit in the `cmd` register is set to 0), the command path state machine sends out a command on the card bus.[†]

Figure 15-6: Command Path State Machine[†]

The command path state machine performs the following functions, according to `cmd` register bit values:[†]

1. `send_initialization`—Initialization sequence of 80 clock cycles is sent before sending the command.[†]
2. `response_expected`—A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start bit of the card response is not received within the number of clock cycles (as set up in the `tmout` register), the `rto` bit and command done (`CD`) bit are set to 1 in the `rintsts` register, to signal to the BIU. If the response-expected bit is set to 0, the command path sends out a command and signals a response done to the BIU, which causes the `cmd` bit to be set to 1 in the `rintsts` register.[†]
3. `response_length`—If this bit is set to 1, a 136-bit long response is received; if it is set to 0, a 48-bit short response is received.[†]
4. `check_response_crc`—If this bit is set to 1, the command path compares CRC-7 received in the response with the internally-generated CRC-7. If the two do not match, the response CRC error is signaled to the BIU, that is, the `rcrc` bit is set to 1 in the `rintsts` register.[†]

Send Response to BIU

If the `response_expected` bit is set to 1 in the `cmd` register, the received response is sent to the BIU. Response register 0 (`resp0`) is updated for a short response, and the response register 3 (`resp3`), response register 2 (`resp2`), response register 1 (`resp1`), and `resp0` registers are updated on a long response, after which the `cmd` bit is set to 1 in the `rintsts` register. If the response is for an `AUTO_STOP` command sent by the CIU, the response is written to the `resp1` register, after which the auto command done bit (`acd`) is set to 1 in the `rintsts` register.[†]

The command path verifies the contents of the card response.

Table 15-11: Card Response Fields[†]

Field	Contents
Response transmission bit	0
Command index	Command index of the sent command
End bit	1

The command index is not checked for a 136-bit response or if the `check_response_crc` bit in the `cmd` register is set to 0. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved, that is, 0b111111.[†]

Related Information

SD Association

For more information about response values, refer to Physical Layer Simplified Specification, Version 3.01 as described on the SD Association website.

Driving P-bit to the CMD Pin

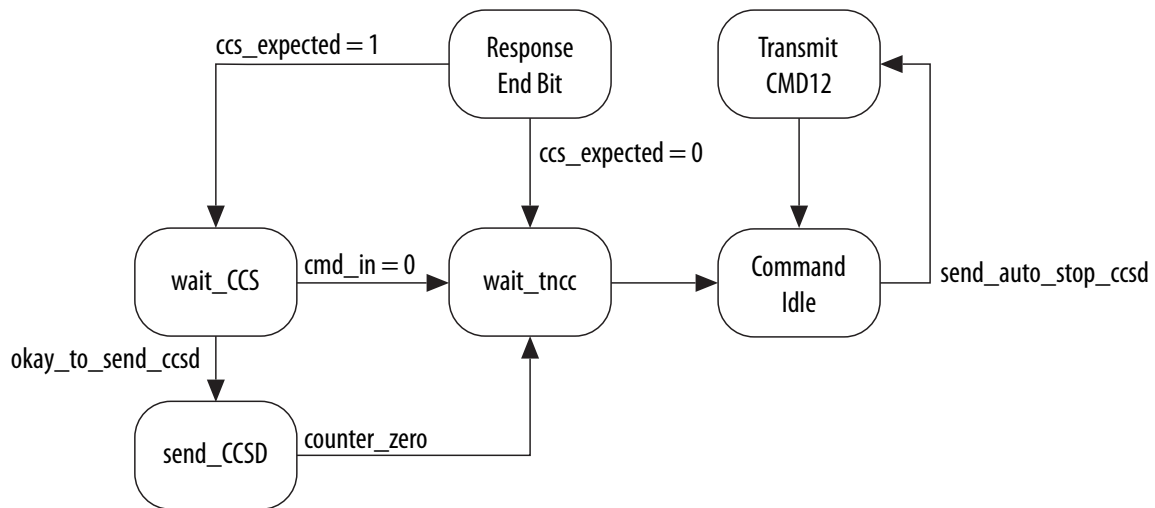

The command path drives a one-cycle pull-up bit (P-bit) to 1 on the `CMD` pin between two commands if a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command. While accessing a CE-ATA card device, for commands that expect a CCS, the P-bit is driven after the response only if the interrupts are disabled in the CE-ATA card (the `nIEN`

bit is set to 1 in the ATA control register), that is, the CCS expected bit (`ccs_expected`) in the `cmd` register is set to 0. If the command expects the CCS, the P-bit is driven only after receiving the CCS.[†]

Polling the CCS

CE-ATA card devices generate the CCS to notify the host controller of the normal ATA command completion or ATA command termination. After receiving the response from the card, the command path state machine performs the functions illustrated in the following figure according to `cmd` register bit values.[†]

Figure 15-7: CE-ATA Command Path State Machine[†]

The above figure illustrates:

- Response end bit state—The state machine receives the end bit of the response from the card device. If the `ccs_expected` bit of the `cmd` register is set to 1, the state machine enters the wait CCS state.[†]
- Wait CCS—The state machine waits for the CCS from the CE-ATA card device. While waiting for the CCS, the following events can happen:[†]
 1. Software sets the send CCSD bit (`send_ccsd`) in the `ctrl` register, indicating not to wait for CCS and to send the CCSD pattern on the command line.[†]
 2. Receive the CCS on the CMD line.[†]
- Send CCSD command—Sends the CCSD pattern (0b00001) on the CMD line.[†]

CCS Detection and Interrupt to Host Processor

If the `ccs_expected` bit in the `cmd` register is set to 1, the CCS from the CE-ATA card device is indicated by setting the data transfer over bit (`dto`) in the `rintsts` register. The controller generates a DTO interrupt if this interrupt is not masked.[†]

For the `RW_MULTIPLE_BLOCK` commands, if the CE-ATA card device interrupts are disabled (the `nIEN` bit is set to 1 in the ATA control register)—that is, the `ccs_expected` bit is set to 0 in the `cmd` register—there are no CCSs from the card. When the data transfer is over—that is, when the requested number of bytes are transferred—the `dto` bit in the `rintsts` register is set to 1.[†]

CCS Timeout

If the command expects a CCS from the card device (the `ccs_expected` bit is set to 1 in the `cmd` register), the command state machine waits for the CCS and remains in the wait CCS state. If the CE-ATA card fails to send out the CCS, the host software must implement a timeout mechanism to free the command and data path. The controller does not implement a hardware timer; it is the responsibility of the host software to maintain a software timer.[†]

In the event of a CCS timeout, the host must issue a CCSD command by setting the `send_ccsd` bit in the `ctrl` register. The controller command path state machine sends the CCSD command to the CE-ATA card device and exits to an idle state. After sending the CCSD command, the host must also send an SD/SDIO `STOP_TRANSMISSION` command to the CE-ATA card to abort the outstanding ATA command.[†]

Send CCSD Command

If the `send_ccsd` bit in the `ctrl` register is set to 1, the controller sends a CCSD pattern on the CMD line. The host can send the CCSD command while waiting for the CCS or after a CCS timeout happens.[†]

After sending the CCSD pattern, the controller sets the `cmd` bit in the `rintsts` register and also generates an interrupt to the host if the Command Done interrupt is not masked.[†]

Note: Within the CIU block, if the `send_ccsd` bit in the `ctrl` register is set to 1 on the same clock cycle as CCS is sampled, the CIU block does not send a CCSD pattern on the CMD line. In this case, the `dto` and `cmd` bits in the `rintsts` register are set to 1.[†]

Note: Due to asynchronous boundaries, the CCS might have already happened and the `send_ccsd` bit is set to 1. In this case, the CCSD command does not go to the CE-ATA card device and the `send_ccsd` bit is not set to 0. The host must reset the `send_ccsd` bit to 0 before the next command is issued.[†]

If the send auto stop CCSD (`send_auto_stop_ccsd`) bit in the `ctrl` register is set to 1, the controller sends an internally generated `STOP_TRANSMISSION` command (CMD12) after sending the CCSD pattern. The controller sets the `acd` bit in the `rintsts` register.[†]

I/O transmission delay (N_{ACIO} Timeout)

The host software maintains the timeout mechanism for handling the I/O transmission delay (N_{ACIO} cycles) time-outs while reading from the CE-ATA card device. The controller neither maintains any timeout mechanism nor indicates that N_{ACIO} cycles are elapsed while waiting for the start bit of a data token. The I/O transmission delay is applicable for read transfers using the `RW_REG` and `RW_BLK` commands; the `RW_REG` and `RW_BLK` commands used in this document refer to the `RW_MULTIPLE_REGISTER` and `RW_MULTIPLE_BLOCK` MMC commands defined by the CE-ATA specification.[†]

Note: After the N_{ACIO} timeout, the application must abort the command by sending the CCSD and `STOP` commands, or the `STOP` command. The Data Read Timeout (DRTO) interrupt might be set to 1 while a `STOP_TRANSMISSION` command is transmitted out of the controller, in which case the data read timeout boot data start bit (`bds`) and the `dto` bit in the `rintsts` register are set to 1.[†]

Data Path

The data path block reads the data FIFO buffer and transmits data on the card bus during a write data transfer, or receives data and writes it to the FIFO buffer during a read data transfer. The data path loads new data parameters—data expected, read/write data transfer, stream/block transfer, block size, byte count, card type, timeout registers—whenever a data transfer command is not in progress. If the data

transfer expected bit (`data_expected`) in the `cmd` register is set to 1, the new command is a data transfer command and the data path starts one of the following actions:[†]

- Transmits data if the read/write bit = 1[†]
- Receives data if read/write bit = 0[†]

Data Transmit

The data transmit state machine starts data transmission two clock cycles after a response for the data write command is received. This occurs even if the command path detects a response error or response CRC error. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the transfer mode bit (`t_transfer_mode`) in the `cmd` register, the data transmit state machine puts data on the card data bus in a stream or in blocks.[†]

Figure 15-8: Data Transmit State Machine[†]

Stream Data Transmit

If the `t_transfer_mode` bit in the `cmd` register is set to 1, the transfer is a stream-write data transfer. The data path reads data from the FIFO buffer from the BIU and transmits in a stream to the card data bus. If the FIFO buffer becomes empty, the card clock is stopped and restarted once data is available in the FIFO buffer.[†]

If the `bytcnt` register is reset to 0, the transfer is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer is terminated when the end bit of the STOP command and end bit of the data match over two clock cycles.[†]

If the `bytcnt` register is written with a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, the STOP command is internally generated and loaded in the command path when the end bit of the STOP command occurs after the last byte of the stream write transfer matches. This data transfer can also terminate if the host issues a STOP command before all the data bytes are transferred to the card bus.[†]

Single Block Data

If the `transfer_mode` bit in the `cmd` register is set to 0 and the `bytcnt` register value is equal to the value of the `block_size` register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated 16-term CRC (CRC-16).[†]

If the `ctype` register is set for a 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.[†]

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This happens when the `dto` bit in the `rintsts` register is set to 1.[†]

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register.[†]

Additionally, if the start bit of the CRC status is not received by two clock cycles after the end of the data block, a CRC status start-bit error (SBE) is signaled to the BIU by setting the `sbe` bit in the `rintsts` register.[†]

Multiple Block Data

A multiple-block write-data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 0 and the value in the `bytcnt` register is not equal to the value of the `block_size` register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC-16 value.[†]

If the `ctype` register is set to 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1-, 4-, or 8-data lines, respectively, and CRC-16 is separately generated and transmitted on 1-, 4-, or 8-data lines, respectively.[†]

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining byte count becomes 0, the data path signals to the BIU that the data transfer is done. This happens when the `dto` bit in the `rintsts` register is set to 1.[†]

If the remaining data bytes are greater than zero, the data path state machine starts to transmit another data block.[†]

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register, and continues further data transmission until all the bytes are transmitted.[†]

If the CRC status start bit is not received by two clock cycles after the end of a data block, a CRC status SBE is signaled to the BIU by setting the `ebe` bit in the `rintsts` register and further data transfer is terminated.[†]

If the `send_auto_stop` bit is set to 1 in the `cmd` register, the SD/SDIO STOP command is internally generated during the transfer of the last data block, where no extra bytes are transferred to the card. The end bit of the STOP command might not exactly match the end bit of the CRC status in the last data block.[†]

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data is transferred, at which time the internally-generated STOP command is loaded in the command path.[†]

If the `bytcnt` is zero (the block size must be greater than zero) the transfer is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.[†]

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. If a response is not received from the card because a response timeout occurs, the BIU does not receive a signal that the data transfer is complete. This happens if the command sent by the controller is an illegal operation for the card, which keeps the card from starting a read data transfer.[†]

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the `transfer_mode` bit in the `cmd` register, the data-receive state machine gets data from the card data bus in a stream or block(s).[†]

Figure 15-9: Data Receive State Machine[†]

Stream Data Read

A stream-read data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 1, at which time the data path receives data from the card and writes it to the FIFO buffer. If the FIFO buffer becomes full, the card clock stops and restarts once the FIFO buffer is no longer full.[†]

An open-ended stream-read data transfer occurs if the `bytcnt` register is set to 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer terminates two clock cycles after the end bit of the STOP command.[†]

If the `bytcnt` register contains a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, a STOP command is internally generated and loaded into the command path, where the end bit of the STOP command occurs after the last byte of the stream data transfer is received. This data transfer can

terminate if the host issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command before all the data bytes are received from the card.[†]

Single-block Data Read

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there is a CRC-16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an End-bit Error (EBE).[†]

Multiple-block Data Read

If the `transfer_mode` bit in the `cmd` register is clear and the value of the `bytcnt` register is not equal to the value of the `block_size` register, the transfer is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC-16.[†]

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining byte count becomes zero, the data path signals a data transfer to the BIU.[†]

If the remaining data bytes are greater than zero, the data path state machine causes another data block to be received. If CRC-16 of a received data block does not match the internally-generated CRC-16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU and the data-receive state machine terminates data reception, waits for data timeout, and signals to the BIU that the data transfer is complete.[†]

If the `send_auto_stop` bit in the `cmd` register is set to 1, the SD/SDIO STOP command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the STOP command might not exactly match the end bit of the last data block.[†]

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data is transferred, at which point the internally-generated STOP command is loaded in the command path. Data received from the card after that are then ignored by the data path.[†]

If the `bytcnt` register is 0 (the block size must be greater than zero), the transfer is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.[†]

Auto-Stop

The controller internally generates an SD/SDIO STOP command and is loaded in the command path when the `send_auto_stop` bit in the `cmd` register is set to 1. The AUTO_STOP command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for SD memory transfer for SD cards. The software must set the `send_auto_stop` bit according to the following details:[†]

The following list describes conditions for the AUTO_STOP command:[†]

- Stream-read for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than six (48 bits), a few extra data bytes are received from the card before the end bit of the STOP command is sent.[†]
- Stream-write for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than six (48 bits), the data path transmits the data last to meet these condition.[†]
- Multiple-block read memory for SD card with byte count greater than zero—If the block size is less than four (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all the bytes are read. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the last data block is received.[†]
- Multiple-block write memory for SD card with byte count greater than zero—If the block size is less than three (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all data blocks are transmitted. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the end bit of the CRC status is received.[†]
- Precaution for host software during auto-stop—When an AUTO_STOP command is issued, the host software must not issue a new command to the controller until the AUTO_STOP command is sent by the controller and the data transfer is complete. If the host issues a new command during a data transfer with the AUTO_STOP command in progress, an AUTO_STOP command might be sent after the new command is sent and its response is received. This can delay sending the STOP command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command, in which case the controller does not generate an AUTO_STOP command.[†]

Auto-Stop Generation for MMC Cards

Table 15-12: Auto-Stop Generation for MMC Cards[†]

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Stream read	0	No	Open-ended stream
Stream read	>0	Yes	Auto-stop after all bytes transfer
Stream write	0	No	Open-ended stream
Stream write	>0	Yes	Auto-stop after all bytes transfer
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 is illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes ^{(48)†}	Pre-defined multiple block

⁽⁴⁸⁾ The condition under which the transfer mode is set to block transfer and byte_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n*block_size (n = 2, 3, ...), the condition is treated as a predefined multiple-block data transfer command. In the case of

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes ^{(48)†}	Pre-defined multiple block

Auto-Stop Generation for SD Cards

Table 15-13: Auto-Stop Generation for SD Cards[†]

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes	Auto-stop after all bytes transfer

Auto-Stop Generation for SDIO Cards

Table 15-14: Auto-Stop Generation for SDIO Cards[†]

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	No	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	No	Pre-defined multiple block

Non-Data Transfer Commands that Use Data Path

Some SD/SDIO non-data transfer commands (commands other than read and write commands) also use the data path.

an MMC card, the host software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the send_auto_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send_auto_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.[†]

Table 15-15: Non-Data Transfer Commands and Requirements[†]

Clock Control Block

The clock control block provides different clock frequencies required for SD/MMC/CE-ATA cards. The clock control block has one clock divider, which is used to generate different card clock frequencies.[†]

The clock frequency of a card depends on the following clock `ctrl` register settings:[†]

⁽⁴⁹⁾ Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.[†]

⁽⁵⁰⁾ Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.[†]

- `clkdiv` register—Internal clock dividers are used to generate different clock frequencies required for the cards. The division factor for the clock divider can be set by writing to the `clkdiv` register. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510; a value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.[†]
- `clksrc` register—Set this register to 0 as clock is divided by clock divider 0.[†]
- `clkena` register—The `cclk_out` card output clock can be enabled or disabled under the following conditions:[†]
 - `cclk_out` is enabled when the `cclk_enable` bit in the `clkena` register is set to 1 and disabled when set to 0.[†]
 - Low-power mode can be enabled by setting the `cclk_low_power` bit of the `clkena` register to 1. If low-power mode is enabled to save card power, the `cclk_out` signal is disabled when the card is idle for at least eight card clock cycles. Low-power mode is enabled when a new command is loaded and the command path goes to a non-idle state.[†]

Under the following conditions, the card clock is stopped or disabled:[†]

- Clock can be disabled by writing to the `clkena` register.[†]
- When low-power mode is selected and the card is idle for at least eight clock cycles.[†]
- FIFO buffer is full, data path cannot accept more data from the card, and data transfer is incomplete—to avoid FIFO buffer overflow.[†]
- FIFO buffer is empty, data path cannot transmit more data to the card, and data transfer is incomplete—to avoid FIFO buffer underflow.[†]

Note: The card clock must be disabled through the `clkena` register before the host software changes the values of the `clkdiv` and `clksrc` registers.[†]

Error Detection

Errors can occur during card operations within the CIU in the following situations.

Response[†]

- Response timeout—did not receive the response expected with response start bit within the specified number of clock cycles in the timeout register.[†]
- Response CRC error—response is expected and check response CRC requested; response CRC-7 does not match with the internally-generated CRC-7.[†]
- Response error—response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.[†]

Data Transmit[†]

- No CRC status—during a write data transfer, if the CRC status start bit is not received for two clock cycles after the end bit of the data block is sent out, the data path performs the following actions:[†]
 - Signals no CRC status error to the BIU[†]
 - Terminates further data transfer[†]
 - Signals data transfer done to the BIU[†]
- Negative CRC—if the CRC status received after the write data block is negative (that is, not 0b010), the data path signals a data CRC error to the BIU and continues with the data transfer.[†]
- Data starvation due to empty FIFO buffer—if the FIFO buffer becomes empty during a write data transmission, or if the card clock stopped and the FIFO buffer remains empty for a data-timeout number of clock cycles, the data path signals a data-starvation error to the BIU and the data path continues to wait for data in the FIFO buffer.[†]

Data Receive

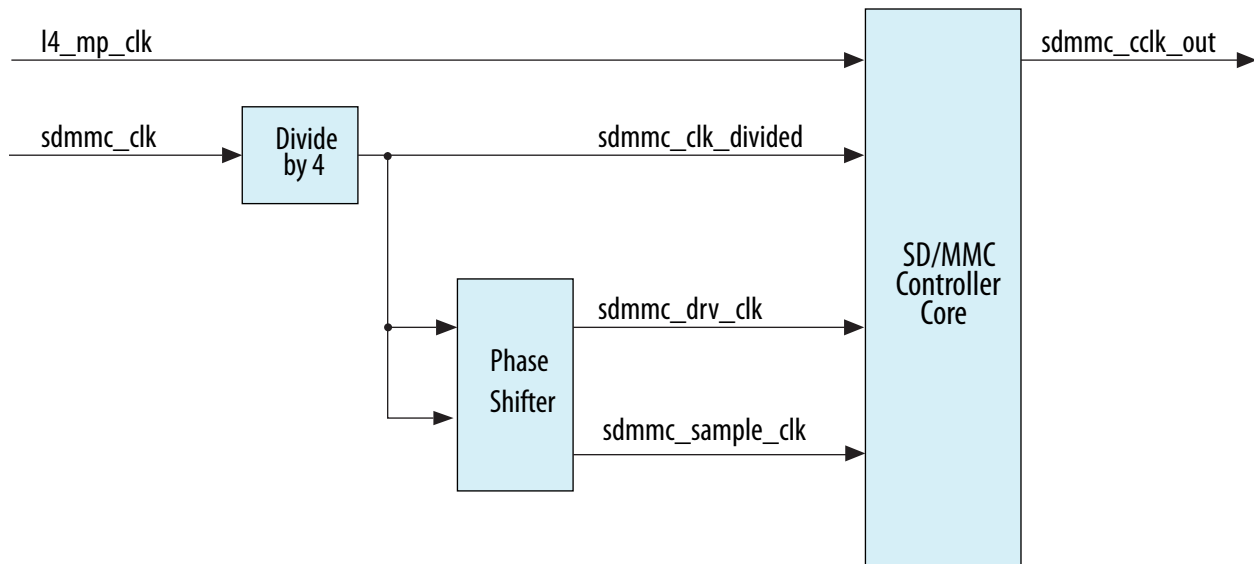

- Data timeout—during a read-data transfer, if the data start bit is not received before the number of clock cycles specified in the timeout register, the data path does the following action: †
 - Signals a data-timeout error to the BIU†
 - Terminates further data transfer†
 - Signals data transfer done to BIU†
- Data SBE—during a 4-bit or 8-bit read-data transfer, if the all-bit data line does not have a start bit, the data path signals a data SBE to the BIU and waits for a data timeout, after which it signals that the data transfer is done.†
- Data CRC error—during a read-data-block transfer, if the CRC-16 received does not match with the internally generated CRC-16, the data path signals a data CRC error to the BIU and continues with the data transfer.†
- Data EBE—during a read-data transfer, if the end bit of the received data is not 1, the data path signals an EBE to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.†
- Data starvation due to FIFO buffer full—during a read data transmission and when the FIFO buffer becomes full, the card clock stops. If the FIFO buffer remains full for a data-timeout number of clock cycles, the data path signals a data starvation error to the BIU, by setting the data starvation host timeout bit (*hto*) in *rintsts* register to 1, and the data path continues to wait for the FIFO buffer to empty.†

Clocks

Table 15-19: SD/MMC Controller Clocks

Clock Name	Direction	Description
<code>l4_mp_clk</code>	In	Clock for SD/MMC controller BIU
<code>sdmmc_clk</code>	In	Clock for SD/MMC controller
<code>sdmmc_cclk_out</code>	Out	Generated output clock for card
<code>sdmmc_clk_divided</code>	Internal	Divide-by-four clock of <code>sdmmc_clk</code>
<code>sdmmc_sample_clk</code>	Internal	Phase-shifted clock of <code>sdmmc_clk_divided</code> used to sample the command and data from the card
<code>sdmmc_drv_clk</code>	Internal	Phase-shifted clock of <code>sdmmc_clk_divided</code> for controller to drive command and data to the card to meet hold time requirements

Figure 15-10: SD/MMC Controller Clock Connections

The `sdmmc_clk` clock from the clock manager is divided by four and becomes the `sdmmc_clk_divided` clock before passing to the phase shifters and the SD/MMC controller CIU. The phase shifters are used to generate the `sdmmc_drv_clk` and `sdmmc_sample_clk` clocks. These phase shifters provide up to eight phases shift which include 0, 45, 90, 135, 180, 225, 270, and 315 degrees. The `sdmmc_sample_clk` clock can be driven by the output from the phase shifter.

Note: The selections of phase shift degree and `sdmmc_sample_clk` source are done in the system manager. For information about setting the phase shift and selecting the source of the `sdmmc_sample_clk` clock, refer to the "Clock Setup" section within this document.

The controller generates the `sdmmc_cclk_out` clock, which is driven to the card. For more information about the generation of the `sdmmc_cclk_out` clock, refer to the "Clock Control Block" section within this document.

Resets

The SD/MMC controller has one reset signal. The reset manager drives this signal to the SD/MMC controller on a cold or warm reset.

Related Information

[Reset Manager](#) on page 4-1

Taking the SD/MMC Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

[Module Reset Signals](#) on page 4-5

Voltage Switching

This section describes the general steps to switch voltage level.

The SD/MMC cards support various operating voltages, for example 1.8V and 3.3V. If you have a card which is at 1.8V and you eject it and replace it with another card, which is 3.3V, then voltage switching is required.

In order to have the right voltage level to power the card, separate devices on the board are required: voltage translation transceiver and power regulator/supply. When the software is aware that voltage switching is needed, it notifies the power regulator that it needs to supply another voltage level to the card (switching between 1.8V and 3.3V).

Many SD cards have an option to signal at 1.8 or 3.3 V, however the initial power-up voltage requirement is 3.3V. To support these different voltage requirements, external transceivers are needed.

The general steps to switch the voltage level requires you to use a SD/MMC voltage-translation transceiver in between the HPS and the SD/MMC card.

Figure 15-11: Voltage Switching Command Flow Diagram[†]

(*1) **Note:** Card returns busy when:[†]

- Card executes internal initialization process[†]
- Card is High or Extended capacity SD Memory Card and host does not support High[†]

The following outlines the steps for the voltage switch programming sequence.[†]

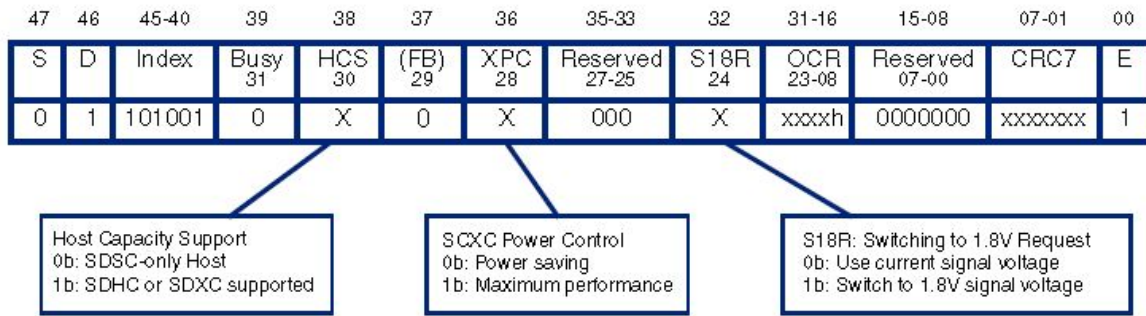

1. Software Driver starts CMD0, which selects the bus mode as SD.[†]
2. After the bus is in SD card mode, CMD8 is started in order to verify if the card is compatible with the SD Memory Card Specification, Version 2.00.[†]

CMD8 determines if the card is capable of working within the host supply voltage specified in the VHS (19:16) field of the CMD; the card supports the current host voltage if a response to CMD8 is received.[†]

3. ACMD 41 is started.[†]

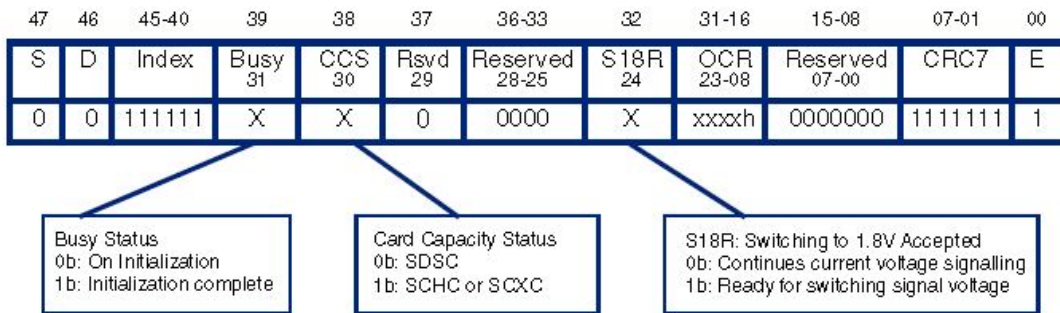

The response to this command informs the software if the card supports voltage switching; bits 38, 36, and 32 are checked by the card argument of ACMD41.[†]

Figure 15-12: ACMD41 Argument

- a. Bit 30 informs the card if host supports SDHC/SDXC or not; this bit should be set to 1'b1.[†]
- b. Bit 28 can be either 1 or 0.[†]
- c. Bit 24 should be set to 1'b1, indicating that the host is capable of voltage switching.[†]

Figure 15-13: ACMD41 Response (R3)[†]

- d. Bit 30 – If set to 1'b1, card supports SDHC/SDXC; if set to 1'b0, card supports only SDSC.[†]
 - e. Bit 24 – If set to 1'b1, card supports voltage switching and is ready for the switch.[†]
 - f. Bit 31 – If set to 1'b1, initialization is over; if set to 1'b0, means initialization in process[†]
4. If the card supports voltage switching, then the software must perform the steps discussed for either the “Voltage Switch Normal Scenario” or the “Voltage Switch Error Scenario”, located in the *Synopsys DesignWare Cores Mobile Storage Host Databook*.

For more information about Voltage Switching

SD/MMC Controller Programming Model

Software and Hardware Restrictions[†]

Only one data transfer command should be issued at one time. For CE-ATA devices, if CE-ATA device interrupts are enabled (nIEN=0), only one RW_MULTIPLE_BLOCK command (RW_BLK) should be

issued; no other commands (including a new RW_BLK) should be issued before the Data Transfer Over status is set for the outstanding RW_BLK.[†]

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.[†]

If the card is enumerated in SDR12 or SDR25 mode, the application must program the `use_hold_reg` bit[29] in the CMD register to 1'b1.[†]

This programming should be done for all data transfer commands and non-data commands that are sent to the card. When the `use_hold_reg` bit is programmed to 1'b0, the SD/MMC controller bypasses the Hold Registers in the transmit path. The value of this bit should not be changed when a Command or Data Transfer is in progress.[†]

For more information on using the `use_hold_reg` and the implementation requirements for meeting the card input hold time, refer to the latest version of the Synopsys DesignWare Cores Mobile Storage Host Databook.

Avoiding Glitches in the Card Clock Outputs[†]

To avoid glitches in the card clock outputs (`sdmmc_cclk_out`), the software should use the following steps when changing the card clock frequency:[†]

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this, check for 0 in bit 9 of the STATUS register.[†]
2. Update the Clock Enable register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:[†]
 - `start_cmd` bit[†]
 - "update clock registers only" bits[†]
 - "wait_previous data complete"[†]

Note: Wait for the CIU to take the command by polling for 0 on the `start_cmd` bit.[†]

3. Set the `start_cmd` bit to update the Clock Divider or Clock Source register, or both, Send a command to the CIU to update the clock registers. Wait for the CIU to take the command.
4. Set `start_cmd` to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.[†]

Reading from a Card in Non-DMA Mode[†]

When a card is read in non-DMA mode, the Data Transfer Over (RINTSTS[3]) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the RX_WMark interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. While using the external DMA interface for reading from a card, the DTO interrupt occurs only after all the data is flushed to memory by the DMA Interface unit.[†]

Writing to a Card in External DMA Mode[†]

While writing to a card in external DMA mode, if an undefined-length transfer is selected by setting the Byte Count register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.[†]

Software Issues a Controller_Reset Command†

If the software issues a `controller_reset` command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued, then:†

- Any pending DMA transfer on the bus completes correctly†
- DMA data read is ignored†
- Write data is unknown (x)†

Additionally, if `dma_reset` is also issued, any pending DMA transfer is abruptly terminated. When the DW-DMA/Non-DW-DMA is used, the DMA controller channel should also be reset and reprogrammed.†

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.†

Data-Transfer Requirement Between the FIFO and Host†

One data-transfer requirement between the FIFO and host is that the number of transfers should be a multiple of the FIFO data width (`F_DATA_WIDTH`). For example, if `F_DATA_WIDTH = 32` and you want to write only 15 bytes to an `SD_MMC_CEATA` card (`BYTCNT`), the host should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers, if external DMA mode is enabled. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the host should still read all 16 bytes from the FIFO.†

It is recommended that you not change the FIFO threshold register in the middle of data transfers when DW-DMA/Non-DW-DMA mode is chosen.†

Initialization†

After the power and clock to the controller are stable, the controller active-low reset is asserted. The reset sequence initializes the registers, FIFO buffer pointers, DMA interface controls, and state machines in the controller.†

Figure 15-14: SD/MMC Controller Initialization Sequence[†]

Power-On Reset Sequence

Software must perform the following steps after the power-on-reset:

1. Before enabling power to the card, confirm that the voltage setting to the voltage regulator is correct. [†]
2. Enable power to the card by setting the power enable bit (`power_enable`) in the power enable register (`pwren`) to 1. Wait for the power ramp-up time before proceeding to the next step. [†]
3. Set the interrupt masks by resetting the appropriate bits to 0 in the `intmask` register. [†]
4. Set the `int_enable` bit of the `ctrl` register to 1. [†]

Note: Intel recommends that you write `0xFFFFFFFF` to the `rintsts` register to clear any pending interrupts before setting the `int_enable` bit to 1. [†]

5. Discover the card stack according to the card type. For discovery, you must restrict the clock frequency to 400 kHz in accordance with SD/MMC/CE-ATA standards. For more information, refer to *Enumerated Card Stack*. [†]
6. Set the clock source assignments. Set the card frequency using the `clkdiv` and `clksrc` registers of the controller. For more information, refer to *Clock Setup*. [†]
7. The following common registers and fields can be set during initialization process: [†]

- The response timeout field (`response_timeout`) of the `tmout` register. A typical value is `0x40`.[†]
- The data timeout field (`data_timeout`) of the `tmout` register, highest of the following:[†]
 - $10 * N_{AC}$ [†]
 N_{AC} = card device total access time[†]
 $= 10 * ((TAAC * F_{OP}) + (100 * NSAC))$ [†]
 where:[†]
 $TAAC$ = Time-dependent factor of the data access time[†]
 F_{OP} = The card clock frequency used for the card operation[†]
 $NSAC$ = Worst-case clock rate-dependent factor of the data access time[†]
 - Host FIFO buffer latency[†]
 On read: Time elapsed before host starts reading from a full FIFO buffer[†]
 On write: Time elapsed before host starts writing to an empty FIFO buffer[†]
 - Debounce counter register (`debncce`). A typical debounce value is 25 ms.[†]
 - TX watermark field (`tx_wmark`) of the FIFO threshold watermark register (`fifoth`). Typically, the threshold value is set to 512, which is half the FIFO buffer depth.[†]
 - RX watermark field (`rx_wmark`) of the `fifoth` register. Typically, the threshold value is set to 511.[†]

These registers do not need to be changed with every SD/MMC/CE-ATA command. Set them to a typical value according to the SD/MMC/CE-ATA specifications.

Related Information

- [Clock Setup](#) on page 15-46
Refer to this section for information on setting the clock source assignments.
- [Enumerated Card Stack](#) on page 15-43
Refer to this section for information on discovering the card stack according to the card type.

Enumerated Card Stack

The card stack performs the following tasks:

- Discovers the connected card[†]
- Sets the relative Card Address Register (RCA) in the connected card[†]
- Reads the card specific information[†]
- Stores the card specific information locally[†]

The card connected to the controller can be an MMC, CE-ATA, SD or SDIO (including IO ONLY, MEM ONLY and COMBO) card.

Identifying the Connected Card Type

To identify the connected card type, the following discovery sequence is needed:

1. Reset the card width 1 or 4 bit (`card_width2`) and card width 8 bit (`card_width1`) fields in the `ctype` register to 0.
2. Identify the card type as SD, MMC, SDIO or SDIO-COMBO:

- a. Send an SD/SDIO `IO_SEND_OP_COND` (CMD5) command with argument 0 to the card.
 - b. Read `resp0` on the controller. The response to the `IO_SEND_OP_COND` command gives the voltage that the card supports.
 - c. Send the `IO_SEND_OP_COND` command, with the desired voltage window in the arguments. This command sets the voltage window and makes the card exit the initialization state.
 - d. Check bit 27 in `resp0`:
 - If bit 27 is 0, the SDIO card is IO ONLY. In this case, proceed to [step 5](#).
 - If bit 27 is 1, the card type is SDIO COMBO. Continue with the following steps.
3. Go to [Card Type is Either SDIO COMBO or Still in Initialization](#) on page 15-44.
 4. Go to [Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device](#) on page 15-45.
 5. At this point, the software has determined the card type as SD/SDHC, SDIO or SDIO-COMBO. Now it must enumerate the card stack according to the type that has been discovered.
 6. Set the card clock source frequency to the frequency of identification clock rate, 400 KHz. Use one of the following discovery command sequences:
 - For an SD card or an SDIO memory section, send the following SD/SDIO command sequence:
 - `GO_IDLE_STATE`
 - `SEND_IF_COND`
 - `SD_SEND_OP_COND` (ACMD41)
 - `ALL_SEND_CID` (CMD2)
 - `SEND_RELATIVE_ADDR` (CMD3)
 - For an SDIO card, send the following command sequence:
 - `IO_SEND_OP_COND`
 - If the function count is valid, send the `SEND_RELATIVE_ADDR` command.
 - For an MMC, send the following command sequence:
 - `GO_IDLE_STATE`
 - `SEND_OP_COND` (CMD1)
 - `ALL_SEND_CID`
 - `SEND_RELATIVE_ADDR`
 7. You can change the card clock frequency after discovery by writing a value to the `clkdiv` register that divides down the `sdmmc_clk` clock.

The following list shows typical clock frequencies for various types of cards:

- SD memory card, 25 MHz[†]
- MMC card device, 12.5 MHz[†]
- Full speed SDIO, 25 MHz[†]
- Low speed SDIO, 400 kHz[†]

Related Information

[SD Association](#)

To learn more about how SD technology works, visit the SD Association website (www.sdcard.org).

Card Type is Either SDIO COMBO or Still in Initialization

Only continue with this step if the SDIO card type is COMBO or there is no response received from the previous `IO_SEND_OP_COND` command. Otherwise, skip to [step 5](#) of the *Identifying the Connected Card Type* section.

1. Send the SD/SDIO `SEND_IF_COND` (CMD8) command with the following arguments:

- Bit[31:12] = 0x0 (reserved bits)[†]
- Bit[11:8] = 0x1 (supply voltage value)[†]
- Bit[7:0] = 0xAA (preferred check pattern by SD memory cards compliant with SDIO Simplified Specification Version 2.00 and later.)[†]

Refer to *SDIO Simplified Specification Version 2.00* as described on the SD Association website.

- If a response is received to the previous SEND_IF_COND command, the card supports SD High-Capacity, compliant with *SD Specifications, Part 1, Physical Layer Simplified Specification Version 2.00*.
 - If no response is received, proceed to **the next decision statement**.
2. Send the SD_SEND_OP_COND (ACMD41) command with the following arguments:
 - Bit[31] = 0x0 (reserved bits)[†]
 - Bit[30] = 0x1 (high capacity status)[†]
 - Bit[29:25] = 0x0 (reserved bits)[†]
 - Bit[24] = 0x1 (S18R --supports voltage switching for 1.8V)[†]
 - Bit[23:0] = supported voltage range[†]
 - If the previous SD_SEND_OP_COND command receives a response, then the card type is SDHC. Otherwise, the card is MMC or CE-ATA. In either case, skip the following steps and proceed to **step 5** of the "Identifying the Connected Card Type" section.
 - If the initial SEND_IF_COND command does not receive a response, then the card does not support High Capacity SD2.0. Now, proceed to **step step 3**.
 3. Next, issue the GO_IDLE_STATE command followed by the SD_SEND_OP_COND command with the following arguments:
 - Bit[31] = 0x0 (reserved bits)[†]
 - Bit[30] = 0x0 (high capacity status)[†]
 - Bit[29:24] = 0x0 (reserved bits)[†]
 - Bit[23:0] = supported voltage range[†]

If a response is received to the previous SD_SEND_OP_COND command, the card is SD type. Otherwise, the card is MMC or CE-ATA.

Note: You must issue the SEND_IF_COND command prior to the first SD_SEND_OP_COND command, to initialize the High Capacity SD memory card. The card returns busy as a response to the SD_SEND_OP_COND command when any of the following conditions are true:

- The card executes its internal initialization process.
- A SEND_IF_COND command is not issued before the SD_SEND_OP_COND command.
- The ACMD41 command is issued. In the command argument, the Host Capacity Support (HCS) bit is set to 0, for a high capacity SD card.

Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device

Use the following sequence to determine whether the card is a CE-ATA 1.1, CE-ATA 1.0, or MMC device:

Determine whether the card is a CE-ATA v1.1 card device by attempting to select ATA mode.

1. Send the SD/SDIO SEND_IF_COND command, querying byte 504 (S_CMD_SET) of the EXT_CSD register block in the external card.

If bit 4 is set to 1, the card device supports ATA mode.

2. Send the `SWITCH_FUNC` (CMD6) command, setting the ATA bit (bit 4) of the `EXT_CSD` register slice 191 (`CMD_SET`) to 1.

This command selects ATA mode and activates the ATA command set.

3. You can verify the currently selected mode by reading it back from byte 191 of the `EXT_CSD` register.
4. Skip to [step 5](#) of the *Identifying the Connected Card Type* section.

If the card device does not support ATA mode, it might be an MMC card or a CE-ATA v1.0 card.

Proceed to the [next section](#) to determine whether the card is a CE-ATA 1.0 card device or an MMC card device.

Determine whether the card is a CE-ATA 1.0 card device or an MMC card device by sending the `RW_REG` command.

If a response is received and the response data contains the CE-ATA signature, the card is a CE-ATA 1.0 card device. Otherwise, the card is an MMC card device.

Clock Setup

The following registers of the SD/MMC controller allow software to select the desired clock frequency for the card:

- `clksrc`
- `clkdiv`
- `clkena`

The controller loads these registers when it receives an update clocks command.

Changing the Card Clock Frequency

To change the card clock frequency, perform the following steps:

1. Before disabling the clocks, ensure that the card is not busy with any previous data command. To do so, verify that the `data_busy` bit of the status register (`status`) is 0.
2. Reset the `cclk_enable` bit of the `clkena` register to 0, to disable the card clock generation.
3. Reset the `clksrc` register to 0.
4. Set the following bits in the `cmd` register to 1:
 - `update_clk_regs_only`—Specifies the update clocks command[†]
 - `wait_prvdata_complete`—Ensures that clock parameters do not change until any ongoing data transfer is complete[†]
 - `start_cmd`—Initiates the command[†]
5. Wait until the `start_cmd` and `update_clk_regs_only` bits change to 0. There is no interrupt when the clock modification completes. The controller does not set the `command_done` bit in the `rintsts` register upon command completion. The controller might signal a hardware lock error if it already has another command in the queue. In this case, return to [Step 4](#).

For information about hardware lock errors, refer to the "Interrupt and Error Handling" chapter.

6. Reset the `sdmmc_clk_enable` bit to 0 in the `enable` register of the clock manager peripheral PLL group (`perpllgrp`).
7. In the control register (`ctrl`) of the SDMMC controller group (`sdmmcgrp`) in the system manager, set the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smp1sel`) bits to specify the required phase shift value.
8. Set the `sdmmc_clk_enable` bit in the `Enable` register of the clock manager `perpllgrp` group to 1.
9. Set the `clkdiv` register of the controller to the correct divider value for the required clock frequency.
10. Set the `cclk_enable` bit of the `clkena` register to 1, to enable the card clock generation.

You can also use the `clkena` register to enable low-power mode, which automatically stops the `sdmmc_cc1k_out` clock when the card is idle for more than eight clock cycles.

Related Information

[Interrupt and Error Handling](#) on page 15-73

Refer to this section for information about hardware lock errors.

Controller/DMA/FIFO Buffer Reset Usage

The following list shows the effect of reset on various parts in the SD/MMC controller:[†]

- Controller reset—resets the controller by setting the `controller_reset` bit in the `ctrl` register to 1. Controller reset resets the CIU and state machines, and also resets the BIU-to-CIU interface. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]
- FIFO buffer reset—resets the FIFO buffer by setting the FIFO reset bit (`fifo_reset`) in the `ctrl` register to 1. FIFO buffer reset resets the FIFO buffer pointers and counters in the FIFO buffer. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]
- DMA reset—resets the internal DMA controller logic by setting the DMA reset bit (`dma_reset`) in the `ctrl` register to 1, which immediately terminates any DMA transfer in progress. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]

Note: Ensure that the DMA is idle before performing a DMA reset. Otherwise, the L3 interconnect might be left in an indeterminate state.[†]

Intel recommends setting the `controller_reset`, `fifo_reset`, and `dma_reset` bits in the `ctrl` register to 1 first, and then resetting the `rintsts` register to 0 using another write, to clear any resultant interrupt.

Enabling ECC

1. Turn on the ECC hardware, but disable the interrupts.
2. Initialize the SRAM in the peripheral.⁽⁵¹⁾
3. Clear the ECC event bits, because these bits may have become asserted after Step 1.
4. Enable the ECC interrupts now that the ECC bits have been set.

Enabling FIFO Buffer ECC

To protect the FIFO buffer data with ECC, you must enable the ECC feature before performing any operations with the SD/MMC controller. Perform the following steps to enable the FIFO buffer ECC feature:

1. Verify there are no commands committed to the controller.
2. Ensure that the FIFO buffer is initialized. Initialize the FIFO buffer by writing 0 to all 1024 FIFO buffer locations. A FIFO buffer write to any address from 0x200 to the maximum FIFO buffer size is valid.
3. Set the SDMMC RAM ECC single and double, correctable error interrupt status bits (`serrporta`, `derrporta`, `serrportb`, and `derrportb`) to 1 in the `sdmmc` register in the `eccgrp` group of the system manager, to clear any previously-detected ECC errors.
4. Reset the FIFO buffer by setting the `fifo_reset` bit to 1 in the `ctrl` register. This action resets pointers and counters in the FIFO buffer. This reset bit is self-clearing, so after issuing the reset, wait until the bit changes to 0.
5. Set the `en` bit in `sdmmc` register in `eccgrp` group of the system manager to 1, to enable ECC for the FIFO buffer in SD/MMC controller.

⁽⁵¹⁾ This is the case for the following peripherals: SD/MMC, NAND, On-Chip, DMA, USB, and EMAC.

Non-Data Transfer Commands

To send any non-data transfer command, the software needs to write the `cmd` register and the `cmdarg` register with appropriate parameters. Using these two registers, the controller forms the command and sends it to the `CMD` pin. The controller reports errors in the command response through the error bits of the `rintsts` register.[†]

When a response is received—either erroneous or valid—the controller sets the `command_done` bit in the `rintsts` register to 1. A short response is copied to `resp0`, while a long response is copied to all four response registers (`resp0`, `resp1`, `resp2`, and `resp3`).[†] For long responses, bit 31 of `resp3` represents the MSB and bit 0 of `resp0` represents the LSB.[†]

For basic and non-data transfer commands, perform the following steps:

1. Write the `cmdarg` register with the appropriate command argument parameter.[†]
2. Write the `cmd` register with the settings in *Register Settings for Non-Data Transfer Command*.[†]
3. Wait for the controller to accept the command. The `start_cmd` bit changes to 0 when the command is accepted.[†]

The following actions occur when the command is loaded into the controller:[†]

- If no previous command is being processed, the controller accepts the command for execution and resets the `start_cmd` bit in the `cmd` register to 0. If a previous command is being processed, the controller loads the new command in the command buffer.[†]
 - If the controller is unable to load the new command—that is, a command is already in progress, a second command is in the buffer, and a third command is attempted—the controller generates a hardware lock error.[†]
4. Check if there is a hardware lock error.[†]
 5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the controller sets the `command_done` bit in the `rintsts` register to 1. Software can either poll for this bit or respond to a generated interrupt (if enabled).[†]
 6. Check if the response timeout boot acknowledge received (`bar`), `rcrc`, or `re` bit is set to 1. Software can either respond to an interrupt raised by these errors or poll the `re`, `rcrc`, and `bar` bits of the `rintsts` register. If no response error is received, the response is valid. If required, software can copy the response from the response registers.[†]

Note: Software cannot modify clock parameters while a command is being executed.[†]

Related Information

[cmd Register Settings for Non-Data Transfer Command[†]](#) on page 15-48

Refer to this table for information about Non-Data Transfer commands.

cmd Register Settings for Non-Data Transfer Command[†]

Table 15-20: Default

Parameter	Value	Comment
<code>start_cmd</code>	1	This bit resets itself to 0 after the command is committed.
<code>use_hold_reg</code>	1 or 0	Choose the value based on the speed mode used.

Parameter	Value	Comment
update_clk_regs_only	0	Indicates that the command is not a clock update command
data_expected	0	Indicates that the command is not a data command
card_number	1	For one card
cmd_index	Command Index	Set this parameter to the command number. For example, set to 8 for the SD/SDIO SEND_IF_COND (CMD8) command.
send_initialization	0 or 1	1 for card reset commands such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0 or 1	1 for a command to stop data transfer, such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
response_length	0 or 1	1 for R2 (long) response 0 for short response
response_expect	0 or 1	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR (CMD4), or GO_INACTIVE_STATE (CMD15). 1 otherwise

Table 15-21: User Selectable

Parameter	Value	Comment
wait_prvdata_complete	1	Before sending a command on the command line, the host must wait for completion of any data command already in process. Intel recommends that you set this bit to 1, unless the current command is to query status or stop data transfer when transfer is in progress.
check_response_crc	1 or 0	1 if the response includes a valid CRC, and the software is required to crosscheck the response CRC bits. 0 otherwise

Data Transfer Commands

Data transfer commands transfer data between the memory card and the controller. To issue a data command, the controller requires a command argument, total data size, and block size. Data transferred to or from the memory card is buffered by the controller FIFO buffer.[†]

Confirming Transfer State

Before issuing a data transfer command, software must confirm that the card is not busy and is in a transfer state, by performing the following steps:[†]

1. Issue an SD/SDIO SEND_STATUS (CMD13) command. The controller sends the status of the card as the response to the command.[†]
2. Check the card's busy status.[†]
3. Wait until the card is not busy.[†]
4. Check the card's transfer status. If the card is in the stand-by state, issue an SD/SDIO SELECT/DESELECT_CARD (CMD7) command to place it in the transfer state.[†]

Busy Signal After CE-ATA RW_BLK Write Transfer

During CE-ATA RW_BLK write transfers, the MMC busy signal might be asserted after the last block. If the CE-ATA card device interrupt is disabled (the nIEN bit in the card device's ATA control register is set to 1), the `dto` bit in the `rintsts` register is set to 1 even though the card sends MMC BUSY. The host cannot issue the CMD60 command to check the ATA busy status after a CMD61 command. Instead, the host must perform one of the following actions:[†]

- Issue the SEND_STATUS command and check the MMC busy status before issuing a new CMD60 command[†]
- Issue the CMD39 command and check the ATA busy status before issuing a new CMD60 command[†]

For the data transfer commands, software must set the `ctype` register to the bus width that is programmed in the card.[†]

Data Transfer Interrupts

The controller generates an interrupt for different conditions during data transfer, which are reflected in the following `rintsts` register bits:[†]

1. `dto`—Data transfer is over or terminated. If there is a response timeout error, the controller does not attempt any data transfer and the Data Transfer Over bit is never set.[†]
2. Transmit FIFO data request bit (`txdr`)—The FIFO buffer threshold for transmitting data is reached; software is expected to write data, if available, into the FIFO buffer.[†]
3. Receive FIFO data request bit (`rxdr`)—The FIFO buffer threshold for receiving data is reached; software is expected to read data from the FIFO buffer.[†]
4. `hto`—The FIFO buffer is empty during transmission or is full during reception. Unless software corrects this condition by writing data for empty condition, or reading data for full condition, the controller cannot continue with data transfer. The clock to the card is stopped.[†]
5. `bds`—The card has not sent data within the timeout period.[†]
6. `dcrc`—A CRC error occurred during data reception.[†]
7. `sbe`—The start bit is not received during data reception.[†]
8. `ebe`—The end bit is not received during data reception, or for a write operation. A CRC error is indicated by the card.[†]

`dcrc`, `sbe`, and `ebe` indicate that the received data might have errors. If there is a response timeout, no data transfer occurs.[†]

Single-Block or Multiple-Block Read

To implement a single-block or multiple-block read, the software performs the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register. For a multi-block read, `bytcnt` must be a multiple of the block size.[†]
2. Write the block size in bytes to the `blksize` register. The controller expects data to return from the card in blocks of size `blksize`.[†]
3. If the read round trip delay, including the card delay, is greater than half of `sdmmc_clk_divided`, write to the card threshold control register (`cardthrcnt1`) to ensure that the card clock does not stop in the middle of a block of data being transferred from the card to the host. For more information, refer to *Card Read Threshold*.[†]

Note: If the card read threshold enable bit (`cardrdthren`) is 0, the host system must ensure that the RX FIFO buffer does not become full during a read data transfer by ensuring that the RX FIFO buffer is read at a rate faster than that at which data is written into the FIFO buffer. Otherwise, an overflow might occur.[†]

4. Write the `cmdarg` register with the beginning data address for the data read.[†]
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Reads*. For SD and MMC cards, use the SD/SDIO READ_SINGLE_BLOCK (CMD17) command for a single-block read and the READ_MULTIPLE_BLOCK (CMD18) command for a multiple-block read. For SDIO cards, use the IO_RW_EXTENDED (CMD53) command for both single-block and multiple-block transfers. The command argument for (CMD53) is shown in the figure, below. After writing to the `cmd` register, the controller starts executing the command. When the command is sent to the bus, the Command Done interrupt is generated.[†]
6. Software must check for data error interrupts, reported in the `dcrc`, `bds`, `sbe`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer by sending an SD/SDIO STOP command.[†]
7. Software must check for host timeout conditions in the `rintsts` register:[†]
 - Receive FIFO buffer data request[†]
 - Data starvation from host—the host is not reading from the FIFO buffer fast enough to keep up with data from the card. To correct this condition, software must perform the following steps:[†]
 - Read the `fifo_count` field of the `status` register[†]
 - Read the corresponding amount of data out of the FIFO buffer[†]

In both cases, the software must read data from the FIFO buffer and make space in the FIFO buffer for receiving more data.[†]

8. When a DTO interrupt is received, the software must read the remaining data from the FIFO buffer.[†]

cmd Register Settings for Single-Block and Multiple-Block Reads†

Table 15-22: cmd Register Settings for Single-Block and Multiple-Block Reads (Default)

Parameter	Value	Comment
start_cmd	1	This bit resets itself to 0 after the command is committed.
use_hold_reg	1 or 0	Choose the value based on speed mode used.
update_clk_regs_only	0	Does not need to update clock parameters
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer

Parameter	Value	Comment
send_initialization	0	1 for a card reset command such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0	1 for a command to stop data transfer such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
send_auto_stop	0 or 1	Refer to <i>Auto Stop</i> for information about how to set this parameter.
read_write	0	Read from card
response_length	0	1 for R2 (long) response 0 for short response
response_expect	1 or 0	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR, and GO_INACTIVE_STATE. 1 otherwise

Table 15-23: cmd Register Settings for Single-Block and Multiple-Block Reads (User Selectable)

Parameter	Value	Comment
wait_prvdata_complete	1 or 0	0 - sends command to CIU immediately 1 - sends command after previous data transfer ends
check_response_crc	1 or 0	0 - Controller must not check response CRC 1 - Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 17 or 18 for SD/SDIO READ_SINGLE_BLOCK (CMD17) or READ_MULTIPLE_BLOCK (CMD18)

Related Information

[Auto-Stop](#) on page 15-29

Refer to this table for information about setting the `send_auto_stop` parameter.

Single-Block or Multiple-Block Write

The following steps comprise a single-block or multiple-block write:

1. Write the data size in bytes to the `bytcnt` register. For a multi-block write, `bytcnt` must be a multiple of the block size.[†]
2. Write the block size in bytes to the `blksiz` register. The controller sends data in blocks of size `blksiz` each.[†]
3. Write the `cmdarg` register with the data address to which data must be written.[†]
4. Write data into the FIFO buffer. For best performance, the host software should write data continuously until the FIFO buffer is full.[†]
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Write*. For SD and MMC cards, use the SD/SDIO WRITE_BLOCK (CMD24) command for a single-block write and the WRITE_MULTIPLE_BLOCK (CMD25) command for a multiple-block writes. For SDIO cards, use the IO_RW_EXTENDED command for both single-block and multiple-block transfers.[†]

After writing to the `cmd` register, the controller starts executing a command if there is no other command already being processed. When the command is sent to the bus, a Command Done interrupt is generated.[†]

6. Software must check for data error interrupts; that is, for `dcrc`, `bds`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer early by sending the SD/SDIO STOP command.[†]
7. Software must check for host timeout conditions in the `rintsts` register:[†]
 - Transmit FIFO buffer data request.[†]
 - Data starvation by the host—the controller wrote data to the card faster than the host could supply the data.[†]

In both cases, the software must write data into the FIFO buffer.[†]

There are two types of transfers: open-ended and fixed length.[†]

- Open-ended transfers—For an open-ended block transfer, the byte count is 0. At the end of the data transfer, software must send the STOP_TRANSMISSION command (CMD12).[†]
- Fixed-length transfers—The byte count is nonzero. You must already have written the number of bytes to the `bytcnt` register. The controller issues the STOP command for you if you set the `send_auto_stop` bit of the `cmd` register to 1. After completion of a transfer of a given number of bytes, the controller sends the STOP command. Completion of the AUTO_STOP command is reflected by the Auto Command Done interrupt. A response to the AUTO_STOP command is written to the `resp1` register. If software does not set the `send_auto_stop` bit in the `cmd` register to 1, software must issue the STOP command just like in the open-ended case.[†]

When the `dto` bit of the `rintsts` register is set, the data command is complete.[†]

cmd Register Settings for Single-Block and Multiple-Block Write

Table 15-24: cmd Register Settings for Single-Block and Multiple-Block Write (Default)[†]

Parameter	Value	Comment
<code>start_cmd</code>	1	This bit resets itself to 0 after the command is committed (accepted by the BIU).
<code>use_hold_reg</code>	1 or 0	Choose the value based on speed mode used.
<code>update_clk_regs_only</code>	0	Does not need to update clock parameters

Parameter	Value	Comment
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer
send_initialization	0	Can be 1, but only for card reset commands such as SD/SDIO GO_IDLE_STATE
stop_abort_cmd	0	Can be 1 for commands to stop data transfer such as SD/SDIO STOP_TRANSMISSION
send_auto_stop	0 or 1	Refer to <i>Auto Stop</i> for information about how to set this parameter.
read_write	1	Write to card
response_length	0	Can be 1 for R2 (long) responses
response_expect	1	Can be 0 for commands with no response. For example, SD/SDIO GO_IDLE_STATE, SET_DSR, GO_INACTIVE_STATE etc.

Table 15-25: cmd Register Settings for Single-Block and Multiple-Block Write (User Selectable)[†]

Parameter	Value	Comment
wait_prvdata_complete	1	0—Sends command to the CIU immediately 1—Sends command after previous data transfer ends
check_response_crc	1	0—Controller must not check response CRC 1—Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).

[Auto-Stop](#) on page 15-29

Refer to this table for information about setting the `send_auto_stop` parameter.

Stream Read and Write

In a stream transfer, if the byte count is equal to 0, the software must also send the SD/SDIO STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the controller sends the STOP command automatically. Completion of this AUTO_STOP command is reflected by the

Auto_command_done interrupt. A response to an AUTO_STOP command is written to the `resp1` register. A stream transfer is allowed only for card interfaces with a 1-bit data bus.[†]

A stream read requires the same steps as the block read described in *Single-Block or Multiple-Block Read*, except for the following bits in the `cmd` register:[†]

- `transfer_mode` = 0x1 (for stream transfer)[†]
- `cmd_index` = 20 (SD/SDIO CMD20)[†]

A stream write requires the same steps as the block write mentioned in *Single-Block or Multiple-Block Write*, except for the following bits in the `cmd` register:[†]

- `transfer_mode` = 0x1 (for stream transfer)[†]
- `cmd_index` = 11 (SD/SDIO CMD11)[†]

Packed Commands

To reduce overhead, read and write commands can be packed in groups of commands—either all read or all write—that transfer the data for all commands in the group in one transfer on the bus. Use the SD/SDIO SET_BLOCK_COUNT (CMD23) command to state ahead of time how many blocks will be transferred. Then issue a single READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command to read or write multiple blocks.[†]

- SET_BLOCK_COUNT—set block count (number of blocks transferred using the READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command)[†]
- READ_MULTIPLE_BLOCK—multiple-block read command[†]
- WRITE_MULTIPLE_BLOCK—multiple-block write command[†]

Packed commands are organized in packets by the application software and are transparent to the controller.[†]

Related Information

[JEDEC Global Standards of the Microelectronics Industry](#)

For more information about packed commands, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

Transfer Stop and Abort Commands

This section describes stop and abort commands. The SD/SDIO STOP_TRANSMISSION command can terminate a data transfer between a memory card and the controller. The ABORT command can terminate an I/O data transfer for only an SDIO card.[†]

STOP_TRANSMISSION (CMD12)

The host can send the STOP_TRANSMISSION (CMD12) command on the CMD pin at any time while a data transfer is in progress. Perform the following steps to send the STOP_TRANSMISSION command to the SD/SDIO card device:[†]

1. Set the `wait_prvdata_complete` bit of the `cmd` register to 0.[†]
2. Set the `stop_abort_cmd` in the `cmd` register to 1, which ensures that the CIU stops.[†]

The `STOP_TRANSMISSION` command is a non-data transfer command.[†]

Related Information

[Non-Data Transfer Commands](#) on page 15-48

Refer to this section for information on the `STOP_TRANSMISSION` command.

ABORT

The ABORT command can only be used with SDIO cards. To abort the function that is transferring data, program the ABORT function number in the `ASx[2:0]` bits at address `0x06` of the card common control register (CCCR) in the card device, using the `IO_RW_DIRECT` (CMD52) command. The CCCR is located at the base of the card space `0x00 – 0xFF`.[†]

Note: The ABORT command is a non-data transfer command.[†]

Related Information

[Non-Data Transfer Commands](#) on page 15-48

Refer to this section for information on the ABORT command.

Sending the ABORT Command

Perform the following steps to send the ABORT command to the SDIO card device:[†]

1. Set the `cmdarg` register to include the appropriate command argument parameters listed in *cmdarg Register Settings for SD/SDIO ABORT Command*.[†]
2. Send the `IO_RW_DIRECT` command by setting the following fields of the `cmd` register:[†]
 - Set the command index to `0x52` (`IO_RW_DIRECT`).[†]
 - Set the `stop_abort_cmd` bit of the `cmd` register to 1 to inform the controller that the host aborted the data transfer.[†]
 - Set the `wait_prvdata_complete` bit of the `cmd` register to 0.[†]
3. Wait for the `cmd` bit in the `rintsts` register to change to 1.[†]
4. Read the response to the `IO_RW_DIRECT` command (R5) in the response registers for any errors.[†]

For more information about response values, refer to the *Physical Layer Simplified Specification, Version 3.01*, available on the SD Association website.

Related Information

cmdarg Register Settings for SD/SDIO ABORT Command[†]

Table 15-26: cmdarg Register Settings for SD/SDIO ABORT Command

Bits	Contents	Value
31	R/W flag	1
30:28	Function number	0, for access to the CCCR in the card device

Bits	Contents	Value
27	RAW flag	1, if needed to read after write
26	Don't care	-
25:9	Register address	0x06
8	Don't care	-
7:0	Write data	Function number to abort

Internal DMA Controller Operations

For better performance, you can use the internal DMA controller to transfer data between the host and the controller. This section describes the internal DMA controller's initialization process, and transmission sequence, and reception sequence.

Internal DMA Controller Initialization

To initialize the internal DMA controller, perform the following steps:[†]

- Set the required `bmod` register bits:[†]
 - If the internal DMA controller enable bit (`de`) of the `bmod` register is set to 0 during the middle of a DMA transfer, the change has no effect. Disabling only takes effect for a new data transfer command.[†]
 - Issuing a software reset immediately terminates the transfer. Prior to issuing a software reset, Intel recommends the host reset the DMA interface by setting the `dma_reset` bit of the `ctrl` register to 1.[†]
 - The `pb1` field of the `bmod` register is read-only and a direct reflection of the contents of the DMA multiple transaction size field (`dw_dma_multiple_transaction_size`) in the `fifoth` register.[†]
 - The `fb` bit of the `bmod` register has to be set appropriately for system performance.[†]
- Write to the `idinten` register to mask unnecessary interrupt causes according to the following guidelines:[†]
 - When a Descriptor Unavailable interrupt is asserted, the software needs to form the descriptor, appropriately set its own bit, and then write to the poll demand register (`pldmnd`) for the internal DMA controller to re-fetch the descriptor.[†]
 - It is always appropriate for the software to enable abnormal interrupts because any errors related to the transfer are reported to the software.[†]
- Populate either a transmit or receive descriptor list in memory. Then write the base address of the first descriptor in the list to the internal DMA controller's descriptor list base address register (`dbaddr`). The DMA controller then proceeds to load the descriptor list from memory. *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences* describe this step in detail.[†]

Related Information

- [Internal DMA Controller Transmission Sequences](#) on page 15-59
Refer to this section for information about the Internal DMA Controller Transmission Sequences.
- [Internal DMA Controller Reception Sequences](#) on page 15-59
Refer to this section for information about the Internal DMA Controller Reception Sequences.

Internal DMA Controller Transmission Sequences

To use the internal DMA controller to transmit data, perform the following steps:

1. The host sets up the Descriptor fields (DES0—DES3) for transmission and sets the OWN bit (DES0[31]) to 1. The host also loads the data buffer in system memory with the data to be written to the SD card.[†]
2. The host writes the appropriate write data command (SD/SDIO WRITE_BLOCK or WRITE_MULTIPLE_BLOCK) to the `cmd` register. The internal DMA controller determines that a write data transfer needs to be performed.[†]
3. The host sets the required transmit threshold level in the `tx_wmark` field in the `fifoth` register.[†]
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters the suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.[†]
5. The host must write the descriptor base address to the `dbaddr` register.[†]
6. The internal DMA controller waits for the Command Done (CD) bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.[†]
7. The internal DMA controller engine waits for a DMA interface request from BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the transmit threshold value.[†]
8. The internal DMA controller fetches the transmit data from the data buffer in the system memory and transfers the data to the FIFO buffer in preparation for transmission to the card.[†]
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor DES0 field indicates whether the data spans multiple descriptors or not.[†]
10. When data transmission is complete, status information is updated in the `idsts` register by setting the `ti` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.[†]

Internal DMA Controller Reception Sequences

To use the internal DMA controller to receive data, perform the following steps:

1. The host sets up the descriptor fields (DES0—DES3) for reception and sets the OWN (DES0 [31]) to 1.[†]
2. The host writes the read data command to the `cmd` register in BIU. The internal DMA controller determines that a read data transfer needs to be performed.[†]
3. The host sets the required receive threshold level in the `rx_wmark` field in the `fifoth` register.[†]
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters suspend state and asserts the Descriptor Unable interrupt. The host then must set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.[†]
5. The host must write the descriptor base address to the `dbaddr` register.[†]
6. The internal DMA controller waits for the CD bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.[†]
7. The internal DMA controller engine waits for a DMA interface request from the BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the receive threshold value.[†]

8. The internal DMA controller fetches the data from the FIFO buffer and transfers the data to system memory.[†]
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.[†]
10. When data reception is complete, status information is updated in the `idsts` register by setting the `ri` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.[†]

Commands for SDIO Card Devices

This section describes the commands to temporarily halt the transfers between the controller and SDIO card device.

Suspend and Resume Sequence

For SDIO cards, a data transfer between an I/O function and the controller can be temporarily halted using the SUSPEND command. This capability might be required to perform a high-priority data transfer with another function. When desired, the suspended data transfer can be resumed using the RESUME command.[†]

The SUSPEND and RESUME operations are implemented by writing to the appropriate bits in the CCCR (Function 0) of the SDIO card. To read from or write to the CCCR, use the controller's IO_RW_DIRECT command.[†]

Suspend

To suspend data transfer, perform the following steps:[†]

1. Check if the SDIO card supports the SUSPEND/RESUME protocol by reading the SBS bit in the CCCR at offset 0x08 of the card.[†]
2. Check if the data transfer for the required function number is in process. The function number that is currently active is reflected in the function select bits (FSx) of the CCCR, bits 3:0 at offset 0x0D of the card.[†]

Note: If the bus status bit (BS), bit 0 at address 0xC, is 1, only the function number given by the FSx bits is valid.[†]

3. To suspend the transfer, set the bus release bit (BR), bit 2 at address 0xC, to 1.[†]
4. Poll the BR and BS bits of the CCCR at offset 0x0C of the card until they are set to 0. The BS bit is 1 when the currently-selected function is using the data bus. The BR bit remains 1 until the bus release is complete. When the BR and BS bits are 0, the data transfer from the selected function is suspended.[†]
5. During a read-data transfer, the controller can be waiting for the data from the card. If the data transfer is a read from a card, the controller must be informed after the successful completion of the SUSPEND command. The controller then resets the data state machine and comes out of the wait state. To accomplish this, set the abort read data bit (`abort_read_data`) in the `ctrl` register to 1.[†]
6. Wait for data completion, by polling until the `dto` bit is set to 1 in the `rintsts` register. To determine the number of pending bytes to transfer, read the transferred CIU card byte count (`tcbcnt`) register of the controller. Subtract this value from the total transfer size. You use this number to resume the transfer properly.[†]

Resume

To resume the data transfer, perform the following steps:[†]

1. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.[†]
2. If the card is in a disconnect state, select it using the SD/SDIO SELECT/DESELECT_CARD command. The card status can be retrieved in response to an IO_RW_DIRECT or IO_RW_EXTENDED command.[†]
3. Check that a function to be resumed is ready for data transfer. Determine this state by reading the corresponding RF<n> flag in CCCR at offset 0x0F of the card. If RF<n> = 1, the function is ready for data transfer.[†]

Note: For detailed information about the RF<n> flags, refer to SDIO Simplified Specification Version 2.00, available on the SD Association website.[†]

4. To resume transfer, use the IO_RW_DIRECT command to write the function number at the FSx bits in the CCCR, bits 3:0 at offset 0x0D of the card. Form the command argument for the IO_RW_DIRECT command and write it to the cmdarg register. Bit values are listed in the following table.[†]

Table 15-27: cmdarg Bit Values for RESUME Command[†]

Bits	Content	Value
31	R/W flag	1
30:28	Function number	0, for CCCR access
27	RAW flag	1, read after write
26	Don't care	-
25:9	Register address	0x0D
8	Don't care	-
7:0	Write data	Function number that is to be resumed

5. Write the block size value to the blksize register. Data is transferred in units of this block size.[†]
6. Write the byte count value to the bytcnt register. Specify the total size of the data that is the remaining bytes to be transferred. It is the responsibility of the software to handle the data.[†]

To determine the number of pending bytes to transfer, read the transferred CIU card byte count register (tcbycnt). Subtract this value from the total transfer size to calculate the number of remaining bytes to transfer.[†]

7. Write to the cmd register similar to a block transfer operation. When the cmd register is written, the command is sent and the function resumes data transfer. For more information, refer to *Single-Block or Multiple-Block Read* and *Single-Block or Multiple-Block Write*.[†]
8. Read the resume data flag (DF) of the SDIO card device. Interpret the DF flag as follows:[†]
 - DF=1—The function has data for the transfer and begins a data transfer as soon as the function or memory is resumed.[†]
 - DF=0—The function has no data for the transfer. If the data transfer is a read, the controller waits for data. After the data timeout period, it issues a data timeout error.[†]

Refer to this section for more information about writing to the `cmd` register.

Read-Wait Sequence

`Read_wait` is used with SDIO cards only. It temporarily stalls the data transfer, either from functions or memory, and allows the host to send commands to any function within the SDIO card device. The host can stall this transfer for as long as required. The controller provides the facility to signal this stall transfer to the card.[†]

Signaling a Stall

To signal the stall, perform the following steps:[†]

1. Check if the card supports the `read_wait` facility by reading the SDIO card's SRW bit, bit 2 at offset 0x8 in the `CCCR`.[†]
2. If this bit is 1, all functions in the card support the `read_wait` facility. Use the SD/SDIO `IO_RW_DIRECT` command to read this bit.[†]
3. If the card supports the `read_wait` signal, assert it by setting the read wait bit (`read_wait`) in the `ctrl` register to 1.[†]
4. Reset the `read_wait` bit to 0 in the `ctrl` register.[†]

CE-ATA Data Transfer Commands

This section describes CE-ATA data transfer commands.

Related Information

[Data Transfer Commands](#) on page 15-50

Refer to this section for information about the basic settings and interrupts generated for different conditions.

ATA Task File Transfer Overview

ATA task file registers are mapped to addresses 0x00h through 0x10h in the MMC register space. The `RW_REG` command is used to issue the ATA command, and the ATA task file is transmitted in a single `RW_REG` MMC command sequence.[†]

The host software stack must write the task file image to the FIFO buffer before setting the `cmdarg` and `cmd` registers in the controller. The host processor then writes the address and byte count to the `cmdarg` register before setting the `cmd` register bits.[†]

For the `RW_REG` command, there is no CCS from the CE-ATA card device.[†]

ATA Task File Transfer Using the `RW_MULTIPLE_REGISTER (RW_REG)` Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer.[†]

Implementing ATA Task File Transfer

To implement an ATA task file transfer (read or write), perform the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register. `bytcnt` must equal the block size, because the controller expects a single block transfer.[†]
2. Write the block size in bytes to the `blksiz` register.[†]
3. Write the `cmdarg` register with the beginning register address.[†]

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the tables in *Register Settings for ATA Task File Transfer*.[†]

Related Information

[Register Settings for ATA Task File Transfer](#) on page 15-63

Refer to this table for information on how to set these registers.

Register Settings for ATA Task File Transfer

Table 15-28: `cmdarg` Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:18	0	Starting register address for read or write (DWORD aligned)
17:16	0	Register address (DWORD aligned)
15:8	0	Reserved (bits set to 0 by host processor)
7:2	16	Number of bytes to read or write (integral number of DWORD)
1:0	0	Byte count in integral number of DWORD

Table 15-29: `cmd` Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
<code>start_cmd</code>	1	
<code>ccs_expected</code>	0	CCS is not expected
<code>read_ceata_device</code>	0 or 1	Set to 1 if <code>RW_BLK</code> or <code>RW_REG</code> read
<code>update_clk_regs_only</code>	0	No clock parameters update command
<code>card_num</code>	0	
<code>send_initialization</code>	0	No initialization sequence
<code>stop_abort_cmd</code>	0	

Bit	Value	Comment
send_auto_stop	0	
transfer_mode	0	Block transfer mode. Block size and byte count must match number of bytes to read or write
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	
response_expect	1	
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	<ul style="list-style-type: none"> 0 for send command immediately 1 for send command after previous DTO interrupt
check_response_crc	1	<ul style="list-style-type: none"> 0 for not checking response CRC 1 for checking response CRC

Table 15-30: blksiz Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	16	For accessing entire task file (16, 8-bit registers). Block size of 16 bytes

Table 15-31: bytcnt Register Settings for ATA Task File Transfer

Bit	Value	Comment
31:0	16	For accessing entire task file (16, 8-bit registers). Byte count value of 16 is used with the block size set to 16.

Reset and Card Device Discovery Overview

Before starting any CE-ATA operations, the host must perform a MMC reset and initialization procedure. The host and card device must negotiate the MMC transfer (MMC TRAN) state before the card enters the MMC TRAN state.[†]

The host must follow the existing MMC discovery procedure to negotiate the MMC TRAN state. After completing normal MMC reset and initialization procedures, the host must query the initial ATA task file values using the RW_REG or CMD39 command.[†]

By default, the MMC block size is 512 bytes—indicated by bits 1:0 of the srcControl register inside the CE-ATA card device. The host can negotiate the use of a 1 KB or 4 KB MMC block sizes. The card indicates MMC block sizes that it can support through the srcCapabilities register in the MMC; the host reads this register to negotiate the MMC block size. Negotiation is complete when the host controller writes the MMC block size into the srcControl register bits 1:0 of the card.[†]

Related Information

JEDEC Global Standards of the Microelectronics Industry

For information about the (MMC TRAN) state, MMC reset and initialization, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

ATA Payload Transfer Using the RW_MULTIPLE_BLOCK (RW_BLK) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer.[†]

Implementing ATA Payload Transfer

To implement an ATA payload transfer (read or write), perform the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register.[†]
2. Write the block size in bytes to the `blksiz` register. The controller expects a single/multiple block transfer.[†]
3. Write to the `cmdarg` register to indicate the data unit count.[†]

Register Settings for ATA Payload Transfer

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the following tables.[†]

Table 15-32: cmdarg Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:16	0	Reserved (bits set to 0 by host processor)
15:8	Data count	Data Count Unit [15:8]
7:0	Data count	Data Count Unit [7:0]

Table 15-33: cmd Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
<code>start_cmd</code>	1	-

Bits	Value	Comment
ccs_expected	1	CCS is expected. Set to 1 for the RW_BLK command if interrupts are enabled in CE-ATA card device (the nIEN bit is set to 0 in the ATA control register)
read_ceata_device	0 or 1	Set to 1 for a RW_BLK or RW_REG read command
update_clk_regs_only	0	No clock parameters update command
card_num	0	-
send_initialization	0	No initialization sequence
stop_abort_cmd	0	-
send_auto_stop	0	-
transfer_mode	0	Block transfer mode. Byte count must be integer multiple of 4kB. Block size can be 512, 1k or 4k bytes
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	-
response_expect	1	-
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	<ul style="list-style-type: none"> 0 for send command immediately 1 for send command after previous DTO interrupt
check_response_crc	1	<ul style="list-style-type: none"> 0 for not checking response CRC 1 for checking response CRC

Table 15-34: blksiz Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
31:16	0	Reserved bits set to 0

Bits	Value	Comment
15:0 (block_size)	512, 1024 or 4096	MMC block size can be 512, 1024 or 4096 bytes as negotiated by host

Table 15-35: bytcnt Register Settings for ATA Payload Transfer

Bits	Value	Comment
31:0	$\langle n \rangle * \text{block_size}$	Byte count must be an integer multiple of the block size. For ATA media access commands, byte count must be a multiple of 4 KB. $(\langle n \rangle * \text{block_size} = \langle x \rangle * 4 \text{ KB},$ where $\langle n \rangle$ and $\langle x \rangle$ are integers)

CE-ATA CCS

This section describes disabling the CCS, recovery after CCS timeout, and recovery after I/O read transmission delay (N_{ACIO}) timeout. †

Disabling the CCS

While waiting for the CCS for an outstanding RW_BLK command, the host can disable the CCS by sending a CCSD command:†

- Send a CCSD command—the controller sends the CCSD command to the CE-ATA card device if the `send_ccsd` bit is set to 1 in the `ctrl` register of the controller. This bit can be set only after a response is received for the RW_BLK command.†
- Send an internal stop command—send an internally-generated SD/SDIO STOP_TRANSMISSION (CMD12) command after sending the CCSD pattern. If the `send_auto_stop_ccsd` bit of the `ctrl` register is also set to 1 when the controller is set to send the CCSD pattern, the controller sends the internally-generated STOP command to the `CMD` pin. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1.†

Recovery after CCS Timeout

If a timeout occurs while waiting for the CCS, the host needs to send the CCSD command followed by a STOP command to abort the pending ATA command. The host can set up the controller to send an internally-generated STOP command after sending the CCSD pattern:†

- Send CCSD command—set the `send_ccsd` bit in the `ctrl` register to 1.†
- Send external STOP command—terminate the data transfer between the CE-ATA card device and the controller. For more information about sending the STOP command, refer to *Transfer Stop and Abort Commands*.†
- Send internal STOP command—set the `send_auto_stop_ccsd` bit in the `ctrl` register to 1, which tells the controller to send the internally-generated STOP command. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1. The `send_auto_stop_ccsd` bit must be set to 1 along with setting the `send_ccsd` bit.†

Related Information

[Transfer Stop and Abort Commands](#) on page 15-56

Refer to this section for more information about sending the STOP command.

Recovery after I/O Read Transmission Delay (N_{ACIO}) Timeout

If the I/O read transmission delay (N_{ACIO}) timeout occurs for the CE-ATA card device, perform one of the following steps to recover from the timeout:[†]

- If the CCS is expected from the CE-ATA card device (that is, the `ccs_expected` bit is set to 1 in the `cmd` register), follow the steps in *Recovery after CCS Timeout*.[†]
- If the CCS is not expected from the CE-ATA card device, perform the following steps:[†]
 1. Send an external STOP command.[†]
 2. Terminate the data transfer between the controller and CE-ATA card device.[†]

Related Information

[Recovery after CCS Timeout](#) on page 15-67

For more information about what steps to take if the CCS is expected from the CE-ATA card device.

Reduced ATA Command Set

It is necessary for the CE-ATA card device to support the reduced ATA command subset. This section describes the reduced command set.[†]

The IDENTIFY DEVICE Command

The IDENTIFY DEVICE command returns a 512-byte data structure to the host that describes device-specific information and capabilities. The host issues the IDENTIFY DEVICE command only if the MMC block size is set to 512 bytes. Any other MMC block size has indeterminate results.[†]

The host issues a `RW_REG` command for the ATA command, and the data is retrieved with the `RW_BLK` command.[†]

The host controller uses the following settings while sending a `RW_REG` command for the IDENTIFY DEVICE ATA command. The following list shows the primary bit settings:[†]

- `cmd` register setting: `data_expected` bit set to 0[†]
- `cmdarg` register settings:[†]
 - Bit [31] set to 0[†]
 - Bits [7:2] set to 128[†]
 - All other bits set to 0[†]
- Task file settings:[†]
 - Command field of the ATA task file set to 0xEC[†]
 - Reserved fields of the task file set to 0[†]
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16[†]

The host controller uses the following settings for data retrieval (`RW_BLK` command):[†]

- cmd register settings:[†]
 - ccs_expected set to 1[†]
 - data_expected set to 1[†]
- cmdarg register settings:[†]
 - Bit [31] set to 0 (read operation)[†]
 - Bits [15:0] set to 1 (data unit count = 1)[†]
 - All other bits set to 0[†]
- bytcnt register and block_size field of the blksize register: set to 512[†]

The READ DMA EXT Command

The READ DMA EXT command reads a number of logical blocks of data from the card device using the Data-In data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.[†]

The WRITE DMA EXT Command

The WRITE DMA EXT command writes a number of logical blocks of data to the card device using the Data-Out data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.[†]

The STANDBY IMMEDIATE Command

This ATA command causes the card device to immediately enter the most aggressive power management mode that still retains internal device context. No data transfer (RW_BLK) is expected for this command.[†]

For card devices that do not provide a power savings mode, the STANDBY IMMEDIATE command returns a successful status indication. The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. Only the status field of the ATA task file contains the success status; there is no error status.[†]

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:[†]

- cmd register setting: data_expected bit set to 0[†]
- cmdarg register settings:[†]
 - Bit [31] set to 1[†]
 - Bits [7:2] set to 4[†]
 - All other bits set to 0[†]
- Task file settings:[†]
 - Command field of the ATA task file set to 0xE0[†]
 - Reserved fields of the task file set to 0[†]
- bytcnt register and block_size field of the blksize register: set to 16[†]

The FLUSH CACHE EXT Command

For card devices that buffer/cache written data, the FLUSH CACHE EXT command ensures that buffered data is written to the card media. For cards that do not buffer written data, the FLUSH CACHE EXT command returns a success status. No data transfer (RW_BLK) is expected for this ATA command.[†]

The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. There can be error status for this ATA command, in which case fields other than the status field of the ATA task file are valid.[†]

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:[†]

- cmd register setting: data_expected bit set to 0[†]
- cmdarg register settings:[†]
 - Bit [31] set to 1[†]
 - Bits [7:2] set to 4[†]
 - All other bits set to 0[†]
- Task file settings:[†]
 - Command field of the ATA task file set to 0xEA[†]
 - Reserved fields of the task file set to 0[†]
- bytcnt register and block_size field of the blksiz register: set to 16[†]

Card Read Threshold

When an application needs to perform a single or multiple block read command, the application must set the cardthrcnt1 register with the appropriate card read threshold size in the card read threshold field (cardrdthreshold) and set the cardrdthren bit to 1. This additional information specified in the controller ensures that the controller sends a read command only if there is space equal to the card read threshold available in the RX FIFO buffer. This in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. Set the card read threshold to the block size of the transfer to guarantee there is a minimum of one block size of space in the RX FIFO buffer before the controller enables the card clock.[†]

The card read threshold is required when the round trip delay is greater than half of sdmmc_clk_divided.[†]

Table 15-36: Card Read Threshold Guidelines[†]

Bus Speed Modes	Round Trip Delay (Delay_R) ⁽⁵²⁾	Is Stopping of Card Clock Allowed?	Card Read Threshold Required?
SDR25	$\text{Delay}_R > 0.5 * (\text{sdmmc_clk}/4)$	No	Yes
	$\text{Delay}_R < 0.5 * (\text{sdmmc_clk}/4)$	Yes	No
SDR12	$\text{Delay}_R > 0.5 * (\text{sdmmc_clk}/4)$	No	Yes
	$\text{Delay}_R < 0.5 * (\text{sdmmc_clk}/4)$	Yes	No

Related Information

[Intel Cyclone V Device Datasheet](#)

⁽⁵²⁾ $\text{Delay}_R = \text{Delay}_O + \text{tODLY} + \text{Delay}_I$ [†]

Where:[†]

$\text{Delay}_O = \text{sdmmc_clk}$ to sdmmc_cclk_out delay (including I/O pin delay)[†]

$\text{Delay}_I = \text{Input I/O pin delay} + \text{routing delay to the input register}$ [†]

$\text{tODLY} = \text{sdmmc_cclk_out}$ to card output delay (varies across card manufactures and speed modes)[†]

For the delay numbers needed for above calculation, refer to Cyclone V Datasheet.[†]

Recommended Usage Guidelines for Card Read Threshold

1. The `cardthrc1` register must be set before setting the `cmd` register for a data read command.[†]
2. The `cardthrc1` register must not be set while a data transfer command is in progress.[†]
3. The `cardrdthreshold` field of the `cardthrc1` register must be set to at the least the block size of a single or multiblock transfer. A `cardrdthreshold` field setting greater than or equal to the block size of the read transfer ensures that the card clock does not stop in the middle of a block of data.[†]
4. If the round trip delay is greater than half of the card clock period, card read threshold must be enabled and the card threshold must be set as per guideline 3 to guarantee that the card clock does not stop in the middle of a block of data.[†]
5. If the `cardrdthreshold` field is set to less than the block size of the transfer, the host must ensure that the receive FIFO buffer never overflows during the read transfer. Overflow can cause the card clock from the controller to stop. The controller is not able to guarantee that the card clock does not stop during a read transfer.[†]

Note: If the `cardrdthreshold` field of the `cardthrc1` register, and the `rx_wmark` and `dw_dma_multiple_transaction_size` fields of the `fifoth` register are set incorrectly, the card clock might stop indefinitely, with no interrupts generated by the controller.[†]

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, support block sizes that are either specified in the card or are fixed to 512 bytes. For SDIO, MMC, and standard capacity SD cards that support partial block read (`READ_BL_PARTIAL` set to 1 in the CSD register of the card device), the block size is variable and can be chosen by the application.[†]

To use the card read threshold feature effectively and to guarantee that the card clock does not stop because of a FIFO Full condition in the middle of a block of data being read from the card, follow these steps:[†]

1. Choose a block size that is a multiple of four bytes.[†]
2. Enable card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than or equal to the total depth of the FIFO buffer:[†]
 $(\text{block size} / 4) \leq 1024$ [†]
3. Choose the card read threshold value:[†]
 - If $(\text{block size} / 4) \geq 512$, choose `cardrdthreshold` such that:[†]
 - `cardrdthreshold` \leq (block size / 4) in bytes[†]
 - If $(\text{block size} / 4) < 512$, choose `cardrdthreshold` such that:[†]
 - `cardrdthreshold` = (block size / 4) in bytes[†]
4. Set the `dw_dma_multiple_transaction_size` field in the `fifoth` register to the number of transfers that make up a DMA transaction. For example, size = 1 means 4 bytes are moved. The possible values for the size are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Select the size so that the value (block size / 4) is evenly divided by the size.[†]
5. Set the `rx_wmark` field in the `fifoth` register to the size - 1.[†]

For example, if your block size is 512 bytes, legal values of `dw_dma_multiple_transaction_size` and `rx_wmark` are listed in the following table.

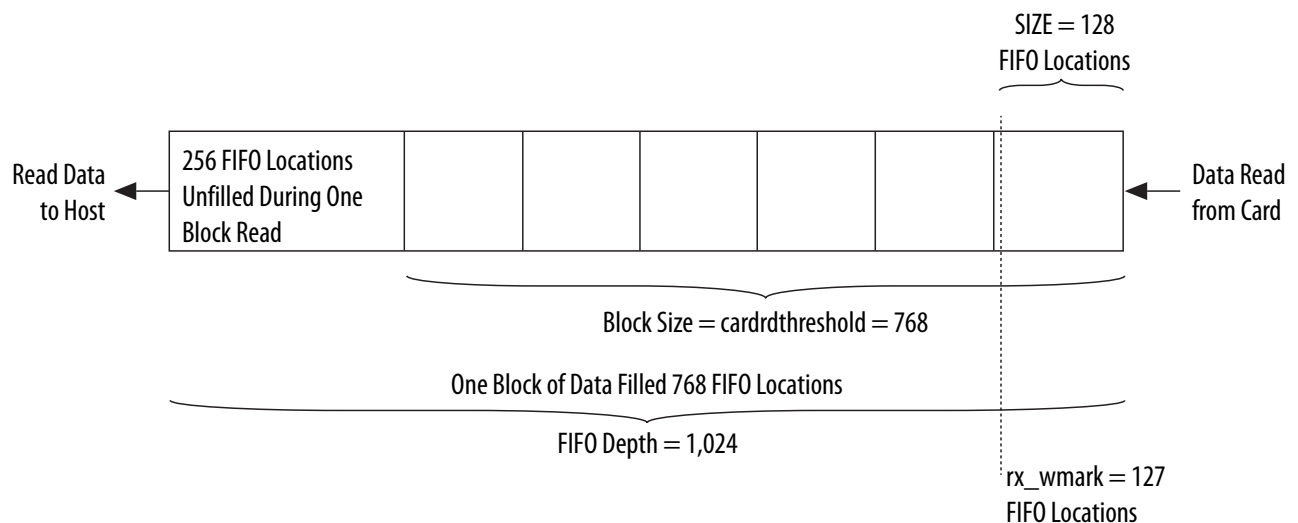

Table 15-37: Legal Values of `dw_dma_multiple_transaction_size` and `rx_wmark` for Block Size = 512[†]

Block Size	<code>dw_dma_multiple_transaction_size</code>	<code>rx_wmark</code>
512	1	0
512	4	3
512	8	7
512	16	15
512	32	31
512	64	63
512	128	127

Card Read Threshold Programming Examples

This section shows examples of how to program the card read threshold.[†]

- Choose a block size that is a multiple of 4 (the number of bytes per FIFO location), and less than 4096 (1024 FIFO locations). For example, a block size of 3072 bytes is legal, because $3072 / 4 = 768$ FIFO locations.[†]
- For DMA mode, choose the size so that block size is a multiple of the size. For example size = 128, where $\text{block size} \% \text{size} = 0$.[†]
- Set the `rx_wmark` field = size - 1. For example, the `rx_wmark` field = $128 - 1 = 127$.[†]
- Because $\text{block size} > \frac{1}{2} \text{FifoDepth}$, set the `cardrdthreshold` field to the block size. For example, the `cardrdthreshold` field = 3072 bytes.[†]

Figure 15-16: FIFO Buffer content when Card Read Threshold is set to 768[†]

Interrupt and Error Handling

This section describes how to use interrupts to handle errors. On power-on or reset, interrupts are disabled (the `int_enable` bit in the `ctrl` register is set to 0), and all the interrupts are masked (the `intmask` register default is 0). The controller error handling includes the following types of errors:

- Response and data timeout errors—For response time-outs, the host software can retry the command. For data time-outs, the controller has not received the data start bit from the card, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `tcrcnt` register later, the software can decide how many bytes remain to be copied (read).[†]
- Response errors—Set to 1 when an error is received during response reception. If the response received is invalid, the software can retry the command.[†]
- Data errors—Set to 1 when a data receive error occurs. Examples of data receive errors:[†]
 - Data CRC[†]
 - Start bit not found[†]
 - End bit not found[†]

These errors can occur on any block. On receipt of an error, the software can issue an SD/SDIO STOP or SEND_IF_COND command, and retry the command for either the whole data or partial data.[†]

- Hardware locked error—Set to 1 when the controller cannot load a command issued by software. When software sets the `start_cmd` bit in the `cmd` register to 1, the controller tries to load the command. If the command buffer already contains a command, this error is raised, and the new command is discarded, requiring the software to reload the command.[†]
- FIFO buffer underrun/overflow error—If the FIFO buffer is full and software tries to write data to the FIFO buffer, an overflow error is set. Conversely, if the FIFO buffer is empty and the software tries to read data from the FIFO buffer, an underrun error is set. Before reading or writing data in the FIFO buffer, the software must read the FIFO buffer empty bit (`fifo_empty`) or FIFO buffer full bit (`fifo_full`) in the `status` register.[†]
- Data starvation by host timeout—This condition occurs when software does not service the FIFO buffer fast enough to keep up with the controller. Under this condition and when a read transfer is in process, the software must read data from the FIFO buffer, which creates space for further data reception. When a transmit operation is in process, the software must write data to fill the FIFO buffer so that the controller can write the data to the card.[†]
- CE-ATA errors[†]
- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.

- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.[†]
- Write operation—Any MMC transport layer error known to the card device causes an outstanding ATA command to be terminated. The ERR bits are set in the ATA status registers and the appropriate error code is sent to the Error Register (Error) on the ATA card device.[†]

If the device interrupt bit of the CE-ATA card (the nIEN bit in the ATA control register) is set to 0, the CCS is sent to the host.[†]

If the device interrupt bit is set to 1, the card device completes the entire data unit count if the host controller does not abort the ongoing transfer.[†]

Note: During a multiple-block data transfer, if a negative CRC status is received from the card device, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register to 1. It then continues further data transmission until all the bytes are transmitted.[†]

- Read operation—If MMC transport layer errors are detected by the host controller, the host completes the ATA command with an error status. The host controller can issue a CCSD command followed by a STOP_TRANSMISSION (CMD12) command to abort the read transfer. The host can also transfer the entire data unit count bytes without aborting the data transfer.[†]

Booting Operation for eMMC and MMC

This section describes how to set up the controller for eMMC and MMC boot operation.

Note: The BootROM and initial software do not use the boot partitions that are in the MMC card. This means that there is no boot partition support of the SD/MMC controller.

Boot Operation by Holding Down the CMD Line

The controller can boot from MMC4.3, MMC4.4, and MMC4.41 cards by holding down the CMD line.

For information about this boot method, refer to the following specifications, available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

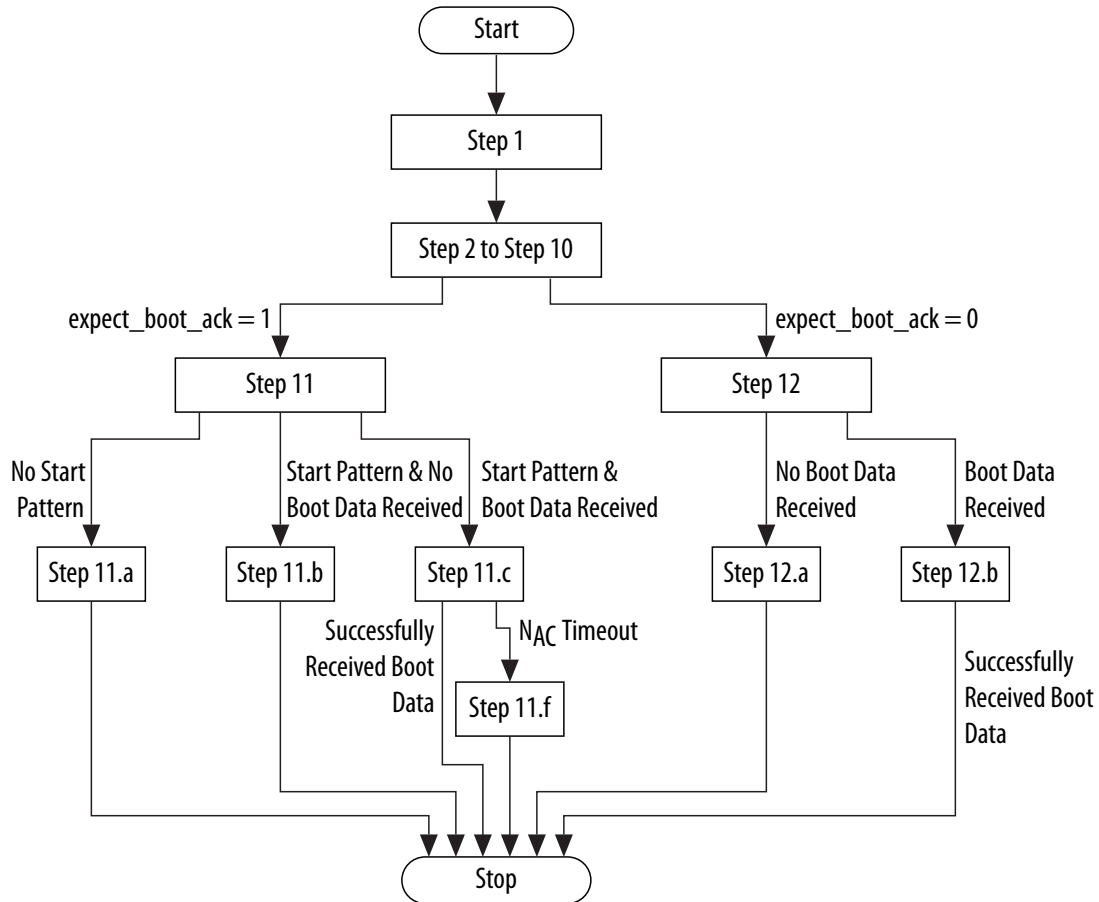

[JEDEC Global Standards of the Microelectronics Industry](#)

For more information about this boot method, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Boot Operation for eMMC Card Device

The following figure illustrates the steps to perform the boot process for eMMC card devices. The detailed steps are described following the flow chart.

Figure 15-17: Flow for eMMC Boot Operation[†]

1. The software driver performs the following checks: [†]
 - If the eMMC card device supports boot operation (the `BOOT_PARTITION_ENABLE` bit is set to 1 in the `EXT_CSD` register of the eMMC card).[†]
 - The `BOOT_SIZE_MULT` and `BOOT_BUS_WIDTH` values in the `EXT_CSD` register, to be used during the boot process.[†]
2. The software sets the following bits: [†]
 - Sets masks for interrupts, by setting the appropriate bits to 0 in the `intmask` register.[†]
 - Sets the global `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0.[†]

Note: Intel recommends that you write `0xFFFFFFFF` to the `rintsts` and `idsts` registers to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.[†]
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following steps: [†]

- Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*.[†]
 - Set the `use_internal_dmac` bit of the `ctrl` register to 1.[†]
4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*.[†]
 5. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC} .[†]
 6. Set the `blksiz` register to 0x200 (512 bytes).[†]
 7. Set the `bytcnt` register to a multiple of 128 KB, as indicated by the `BOOT_SIZE_MULT` value in the card device.[†]
 8. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.[†]
 9. Set the following fields in the `cmd` register:[†]
 - Initiate the command by setting `start_cmd` = 1[†]
 - Enable boot (`enable_boot`) = 1[†]
 - Expect boot acknowledge (`expect_boot_ack`):[†]
 - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.[†]
 - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.[†]
 - Card number (`card_number`) = 0[†]
 - `data_expected` = 1[†]
 - Reset the remainder of `cmd` register bits to 0[†]
 10. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) proceed to [step 12](#).[†]
 11. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in [step 9](#)).[†]
 - a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command ([step 9](#)), the software driver must set the following `cmd` register fields:[†]
 - `start_cmd` = 1[†]
 - Disable boot (`disable_boot`) = 1[†]
 - `card_number` = 0[†]
 - All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

- The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set, indicating the Boot ACK Received timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
- b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to the `ces` bit in the `idsts` register.[†]

Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must write the following `cmd` register fields:[†]

- `start_cmd` = 1[†]
- `disable_boot` = 1[†]
- `card_number` = 0[†]
- All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

- The DMA descriptor is closed[†]
 - The `ces` bit in the `idsts` register is set, indicating Boot Data Start timeout[†]
 - The `ri` bit of the `idsts` register is not set[†]
- c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.[†]

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level set in the `rx_wmark` field of the `fifoth` register is reached.[†]

At the end of a successful boot data transfer from the card, the following interrupts are generated:[†]

- The `cmd` bit and `dto` bit in the `rintsts` register[†]
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only[†]
- d. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs:[†]
- The controller automatically aborts the boot process by pulling the `CMD` line high[†]
 - The controller generates a Command Done interrupt[†]
 - The controller does not generate a Boot ACK Received interrupt[†]
 - The application aborts the boot transfer[†]
- e. In internal DMA controller mode:[†]
- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. Software cannot reuse the descriptors until they are closed.[†]
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.[†]
- f. If N_{AC} is violated between data block transfers, the `DRTO` interrupt is asserted. In addition, if there is an error associated with the start or end bit, the `SBE` or `EBE` interrupt is also generated.[†]

The boot operation for eMMC card devices is complete. Do not execute the remaining (**step 12**).[†]

12. This step handles the case where no start-acknowledge pattern is expected (`expect_boot_ack` was set to 0 in **step 9**).[†]

- a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 9**), the software driver must write the `cmd` register with the following fields:[†]
- `start_cmd` = 1[†]
 - `disable_boot` = 1[†]
 - `card_number` = 0[†]
 - All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` line of the card. In internal DMA controller mode, the descriptor is closed and the `ces` bit in the `idsts` register is set to 1, indicating a Boot Data Start timeout.[†]

- b. If a Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver

can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.[†]

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.[†]

At the end of a successful boot data transfer from the card, the following interrupts are generated:[†]

- The `cmd` bit and `dto` bit in the `rintsts` register[†]
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only[†]
- c. In internal DMA controller mode:[†]
- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.[†]
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.[†]

The boot operation for eMMC card devices is complete.[†]

Boot Operation for Removable MMC4.3, MMC4.4 and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 Differences

Removable MMC4.3, MMC4.4, and MMC4.41 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation when plugged in. Thus, the controller must:[†]

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time[†]
2. Know the card characteristics[†]
3. Decide whether to perform a boot operation or not[†]

Bootable Removable MMC4.3, MMC4.4 and MMC4.41 Cards

For removable MMC4.3, MMC4.4 and MMC4.41 cards, the software driver must perform the following steps:[†]

1. Discover the card as described in *Enumerated Card Stack*.[†]
2. Read the EXT_CSD register of the card and examine the following fields:[†]
 - `BOOT_PARTITION_ENABLE`[†]
 - `BOOT_SIZE_MULT`[†]
 - `BOOT_INFO`[†]
3. If necessary, the software can manipulate the boot information in the card.[†]

Note: For more information, refer to “Access to Boot Partition” in the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
 - JEDEC Standard No. 84-A44
 - JEDEC Standard No. JESD84-A43
4. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH_FUNC command. †
 5. After this step, the software driver must power down the card by writing to the `pwr_en` register. †
 6. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*. †

Related Information

- [Enumerated Card Stack](#) on page 15-43

- [Alternative Boot Operation for eMMC Card Devices](#) on page 15-79
Refer to this section for information about alternative boot operation steps.

Alternative Boot Operation

The alternative boot operation differs from the previous boot operation in that software uses the SD/SDIO GO_IDLE_STATE command to boot the card, rather than holding down the CMD line of the card. The alternative boot operation can be performed only if bit 0 in the BOOT_INFO register is set to 1. BOOT_INFO is located at offset 228 in the EXT_CSD registers. †

For detailed information about alternative boot operation, refer to the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

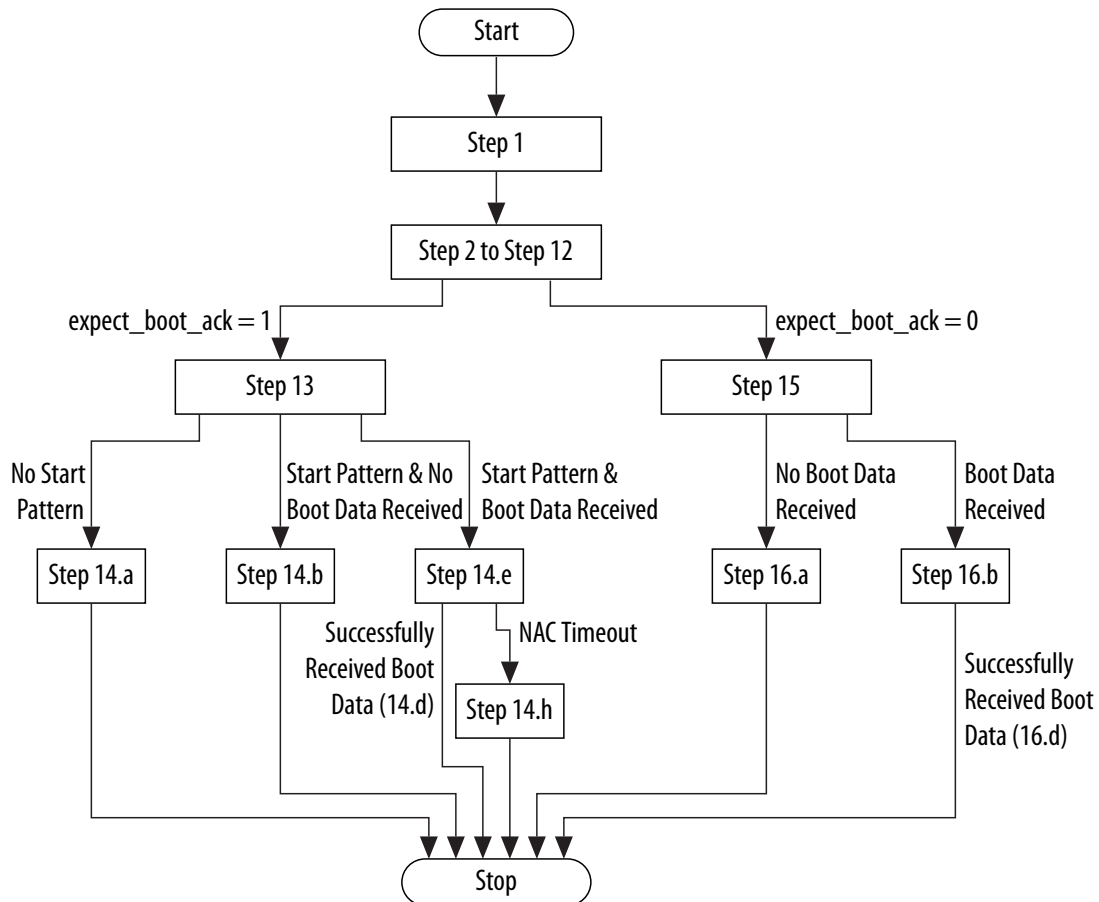

Related Information

[JEDEC Global Standards of the Microelectronics Industry](#)

For more information about alternative boot operation, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Alternative Boot Operation for eMMC Card Devices

The following figure illustrates the sequence of steps required to perform the alternative boot operation for eMMC card devices. The detailed steps are described following the flow chart.

Figure 15-18: Flow for eMMC Alternative Boot Operation[†]

1. The software driver checks:[†]
 - If the eMMC card device supports alternative boot operation (the `BOOT_INFO` bit is set to 1 in the eMMC card).[†]
 - The `BOOT_SIZE_MULT` and `BOOT_BUS_WIDTH` values in the card device to use during the boot process.[†]
2. The software sets the following bits:[†]
 - Sets masks for interrupts by resetting the appropriate bits to 0 in the `intmask` register.[†]
 - Sets the `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0.[†]

Note: Intel recommends writing `0xFFFFFFFF` to the `rintsts` register and `idsts` register to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.[†]
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following actions:[†]
 - Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*.[†]
 - Set the use internal DMAC bit (`use_internal_dmac`) of the `ctrl` register to 1.[†]
4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*. Ensure that the card clock is running.[†]

5. Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.[†]
6. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC} .[†]
7. Set the `blksiz` register to 0x200 (512 bytes).[†]
8. Set the `bytcnt` register to multiples of 128K bytes, as indicated by the `BOOT_SIZE_MULT` value in the card device.[†]
9. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.[†]
10. Set the `cmdarg` register to 0xFFFFFFFF.[†]
11. Initiate the command, by setting the `cmd` register with the following fields:[†]
 - `start_cmd` = 1[†]
 - `enable_boot` = 1[†]
 - `expect_boot_ack`:[†]
 - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.[†]
 - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.[†]
 - `card_number` = 0[†]
 - `data_expected` = 1[†]
 - `cmd_index` = 0[†]
 - Set the remainder of `cmd` register bits to 0.[†]
12. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) jump to [step 15](#).[†]
13. Wait for the Command Done interrupt.[†]
14. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in [step 11](#)).[†]
 - a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command ([step 11](#)), the start pattern was not received. The software driver must discontinue the boot process and start with normal discovery.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

 - The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set to 1, indicating the Boot ACK Received timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
 - b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to it.[†]

Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must discontinue the boot process and start with normal discovery.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

 - The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
 - c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.[†]

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

- d. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE command: †
 - Reset the `cmdarg` register to 0. †
 - Set the `start_cmd` bit of the `cmd` register to 1, and all other bits to 0. †
- e. At the end of a successful boot data transfer from the card, the following interrupts are generated: †
 - The `cmd` bit and `dto` bit in the `rintsts` register †
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only †
- f. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †
 - The controller does not generate a Boot ACK Received interrupt. †
 - The controller detects Boot Data Start and generates a Boot Data Start interrupt. †
 - The controller continues to receive boot data. †
 - The application must abort the boot process after receiving a Boot Data Start interrupt. †
- g. In internal DMA controller mode: †
 - If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory. †
- h. If N_{AC} is violated between data block transfers, a DRTO interrupt is asserted. Apart from this, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated. †

The alternative boot operation for eMMC card devices is complete. Do not execute the remaining steps (15 and 16). †

15. Wait for the Command Done interrupt. †

16. This step handles the case where a start-acknowledge pattern is not expected (`expect_boot_ack` was set to 0 in [step 11](#)). †

- a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command ([step 11](#)), the software driver must discontinue the boot process and start with normal discovery. † In internal DMA controller mode: †
 - The DMA descriptor is closed. †
 - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout. †
 - The `ri` bit of the `idsts` register is not set. †
- b. If a Boot Data Start interrupt is received, the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register. †

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

- c. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE (CMD0) command: †
 - Reset the `cmdarg` register to 0. †
 - Set the `start_cmd` bit in the `cmd` register to 1, and all other bits to 0. †
- d. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The `cmd` bit and `dto` bit in the `rintsts` register[†]
- The `ri` bit in the `idsts` register, in internal DMA controller mode only[†]
- e. In internal DMA controller mode:[†]
 - If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.[†]
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.[†]

The alternative boot operation for eMMC card devices is complete.[†]

Alternative Boot Operation for MMC4.3 Cards

Removable MMC4.3 Boot Mode Support

Removable MMC4.3 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation. Thus, the controller must:[†]

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time[†]
2. Know the card characteristics[†]
3. Decide whether to perform a boot operation or not[†]

Discovering Removable MMC4.3 Boot Mode Support

For removable MMC4.3 cards, the software driver must perform the following steps:[†]

1. Discover the card as described in *Enumerated Card Stack*.[†]
2. Read the MMC card device's EXT_CSD registers and examine the following fields:[†]
 - `BOOT_PARTITION_ENABLE`[†]
 - `BOOT_SIZE_MULT`[†]
 - `BOOT_INFO`[†]

Note: For more information, refer to "Access to Boot Partition" in JEDEC Standard No. JESD84-A43, available on the JEDEC website.[†]

3. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the contents of the EXT_CSD registers in the MMC card device, by using a `SWITCH_FUNC` command.[†]
4. After this step, the software driver must power down the card by writing to the `pwren` register.[†]
5. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*.[†]

Note: Ignore the EBE if it is generated during an abort scenario.

If a boot acknowledge error occurs, the boot acknowledge received interrupt times out.[†]

In internal DMA controller mode, the application needs to depend on the descriptor close interrupt instead of the data done interrupt. †

Value	Description									
0x0	The host performs data transfers thru slave interface									
0x1	Internal DMAC used for data transfer									
11	ceata_device_interrupt_status	<p>Software should appropriately write to this bit after power-on reset or any other reset to CE-ATA device. After reset, usually CE-ATA device interrupt is disabled (nIEN = 1). If the host enables CE-ATA device interrupt, then software should set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Interrupts not enabled in CE-ATA device</td> </tr> <tr> <td>0x1</td> <td>Interrupts are enabled in CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Interrupts not enabled in CE-ATA device	0x1	Interrupts are enabled in CE-ATA device	RW	0x0
Value	Description									
0x0	Interrupts not enabled in CE-ATA device									
0x1	Interrupts are enabled in CE-ATA device									
10	send_auto_stop_ccsd	<p>Always set send_auto_stop_ccsd and send_ccsd bits together; send_auto_stop_ccsd should not be set independent of send_ccsd. When set, SD/MMC automatically sends internally generated STOP command (CMD12) to CE-ATA device. After sending internally-generated STOP command, Auto Command Done (ACD) bit in RINTSTS is set and generates interrupt to host if Auto CommandDone interrupt is not masked. After sending the CCSD, SD/MMC automatically clears send_auto_stop_ccsd bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Clear bit if SD/MMC does not reset the bit</td> </tr> <tr> <td>0x1</td> <td>Send internally generated STOP.</td> </tr> </tbody> </table>	Value	Description	0x0	Clear bit if SD/MMC does not reset the bit	0x1	Send internally generated STOP.	RW	0x0
Value	Description									
0x0	Clear bit if SD/MMC does not reset the bit									
0x1	Send internally generated STOP.									

Bit	Name	Description	Access	Reset						
9	send_ccsd	<p>When set, SD/MMC sends CCSD to CE-ATA device. Software sets this bit only if current command is expecting CCS (that is, RW_BLK) and interrupts are enabled in CE-ATA device. Once the CCSD pattern is sent to device, SD/MMC automatically clears send_ccsd bit. It also sets Command Done (CD) bit in RINTSTS register and generates interrupt to host if Command Done interrupt is not masked. NOTE: Once send_ccsd bit is set, it takes two card clock cycles to drive the CCSD on the CMD line. Due to this, during the boundary conditions it may happen that CCSD is sent to the CE-ATA device, even if the device signalled CCS.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Clear bit if SD/MMC does not reset the bit</td> </tr> <tr> <td>0x1</td> <td>Send Command Completion Signal Disable (CCSD) to CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Clear bit if SD/MMC does not reset the bit	0x1	Send Command Completion Signal Disable (CCSD) to CE-ATA device	RW	0x0
Value	Description									
0x0	Clear bit if SD/MMC does not reset the bit									
0x1	Send Command Completion Signal Disable (CCSD) to CE-ATA device									
8	abort_read_data	<p>After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data statemachine resets to idle. Used in SDIO card suspend sequence.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Abort Read</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Abort Read	RW	0x0
Value	Description									
0x0	No change									
0x1	Abort Read									
7	send_irq_response	<p>Bit automatically clears once response is sent. To wait for MMC card interrupts, host issues CMD40, and SD/MMC waits for interrupt response from MMC card(s). In meantime, if host wants SD/MMC to exit waiting for interrupt state, it can set this bit, at which time SD/MMC command state-machine sends CMD40 response on bus and returns to idle state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Send auto IRQ response</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Send auto IRQ response	RW	0x0
Value	Description									
0x0	No change									
0x1	Send auto IRQ response									

Bit	Name	Description	Access	Reset						
6	read_wait	For sending read-wait to SDIO cards. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Read Wait</td> </tr> <tr> <td>0x1</td> <td>Assert Read Wait</td> </tr> </tbody> </table>	Value	Description	0x0	Read Wait	0x1	Assert Read Wait	RW	0x0
Value	Description									
0x0	Read Wait									
0x1	Assert Read Wait									
4	int_enable	This bit enables and disable interrupts if one or more unmasked interrupts are set. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disable Interrupts</td> </tr> <tr> <td>0x1</td> <td>Enable interrupts</td> </tr> </tbody> </table>	Value	Description	0x0	Disable Interrupts	0x1	Enable interrupts	RW	0x0
Value	Description									
0x0	Disable Interrupts									
0x1	Enable interrupts									
2	dma_reset	This bit resets the DMA interface control logic <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Reset internal DMA interface control logic</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Reset internal DMA interface control logic	RW	0x0
Value	Description									
0x0	No change									
0x1	Reset internal DMA interface control logic									
1	fifo_reset	This bit resets the FIFO. This bit is auto-cleared after completion of reset operation. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Reset to data FIFO To reset FIFO pointers</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Reset to data FIFO To reset FIFO pointers	RW	0x0
Value	Description									
0x0	No change									
0x1	Reset to data FIFO To reset FIFO pointers									
0	controller_reset	This bit resets the controller. This bit is auto-cleared after two l4_mp_clk and two sdmmc_clk clock cycles. This resets: - BIU/CIU interface - CIU and state machines - abort_read_data, send_irq_response, and read_wait bits of control register -start_cmd bit of command register Does not affect any registers, DMA interface, FIFO or host interrupts. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change -default</td> </tr> <tr> <td>0x1</td> <td>Reset SD/MMC controller</td> </tr> </tbody> </table>	Value	Description	0x0	No change -default	0x1	Reset SD/MMC controller	RW	0x0
Value	Description									
0x0	No change -default									
0x1	Reset SD/MMC controller									

pwren

Power on/off switch for card; once power is turned on, firmware should wait for regulator/switch ramp-up time before trying to initialize card.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704004

Offset: 0x4

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															power_ enable RW 0x0

pwren Fields

Bit	Name	Description	Access	Reset						
0	power_enable	Power on/off switch for one card; for example, bit[0] controls the card. Once power is turned on, firmware should wait for regulator/switch ramp-up time before trying to initialize card.	RW	0x0						
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Power Off</td> </tr> <tr> <td>0x1</td> <td>Power On</td> </tr> </tbody> </table>	Value	Description	0x0	Power Off	0x1	Power On		
Value	Description									
0x0	Power Off									
0x1	Power On									

clkdiv

Divides Clock sdmmc_clk.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704008

Offset: 0x8

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								clk_divider0 RW 0x0							

clkdiv Fields

Bit	Name	Description	Access	Reset
7:0	clk_divider0	Clock divider-0 value. Clock division is 2^n . For example, value of 0 means divide by $2^0 = 1$ (no division, bypass), value of 1 means divide by $2^1 = 2$, value of ff means divide by $2^{255} = 510$, and so on.	RW	0x0

clksrc

Selects among available clock dividers. The sdmmc_cclk_out is always from clock divider 0.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF70400C

Offset: 0xC

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													clk_source RW 0x0		

clksrc Fields

Bit	Name	Description	Access	Reset				
1:0	clk_source	Selects among available clock dividers. The SD/MMC module is configured with just one clock divider so this register should always be set to choose clkdiv0.	RW	0x0				
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Clock divider 0</td> </tr> </tbody> </table>	Value	Description	0x0	Clock divider 0		
Value	Description							
0x0	Clock divider 0							

clkena

Controls external SD/MMC Clock Enable.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704010

Offset: 0x10

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															cclk_low_power RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															cclk_enable RW 0x0

clkena Fields

Bit	Name	Description	Access	Reset						
16	cclk_low_power	In low-power mode, stop sdmmc_cclk_out when card in IDLE (should be normally set to only MMC and SD memory cards; for SDIO cards, if interrupts must be detected, clock should not be stopped). <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Non-low-power mode</td> </tr> <tr> <td>0x1</td> <td>Low-power mode</td> </tr> </tbody> </table>	Value	Description	0x0	Non-low-power mode	0x1	Low-power mode	RW	0x0
Value	Description									
0x0	Non-low-power mode									
0x1	Low-power mode									
0	cclk_enable	Enables sdmmc_cclk_out. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SD/MMC Disable</td> </tr> <tr> <td>0x1</td> <td>SD/MMC Enable</td> </tr> </tbody> </table>	Value	Description	0x0	SD/MMC Disable	0x1	SD/MMC Enable	RW	0x0
Value	Description									
0x0	SD/MMC Disable									
0x1	SD/MMC Enable									

tmout

Sets timeout values

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704014

Offset: 0x14

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
data_timeout RW 0xFFFFFFFF															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
data_timeout RW 0xFFFFFFFF								response_timeout RW 0x40							

tmout Fields

Bit	Name	Description	Access	Reset
31:8	data_timeout	Value for card Data Read Timeout; same value also used for Data Starvation by Host timeout. Value is in number of card output clocks sdmmc_cclk_out of selected card.	RW	0xFFFFFFFF F
7:0	response_timeout	Response timeout value. Value is in number of card output clocks sdmmc_cclk_out.	RW	0x40

ctype

Describes card formats.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704018

Offset: 0x18

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															card_width1 RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															card_width2 RW 0x0

ctype Fields

Bit	Name	Description	Access	Reset						
16	card_width1	Indicates if card is 8 bit or othersize. If not 8-bit, card_width2 specifies the width. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Non 8-bit mode</td> </tr> <tr> <td>0x1</td> <td>8-bit mode</td> </tr> </tbody> </table>	Value	Description	0x0	Non 8-bit mode	0x1	8-bit mode	RW	0x0
Value	Description									
0x0	Non 8-bit mode									
0x1	8-bit mode									
0	card_width2	Ignored if card_width1 is MODE8BIT. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>1-bit mode</td> </tr> <tr> <td>0x1</td> <td>4-bit mode</td> </tr> </tbody> </table>	Value	Description	0x0	1-bit mode	0x1	4-bit mode	RW	0x0
Value	Description									
0x0	1-bit mode									
0x1	4-bit mode									

blksiz

The Block Size.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF70401C

Offset: 0x1C

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
block_size															
RW 0x200															

blksiz Fields

Bit	Name	Description	Access	Reset
15:0	block_size	The size of a block in bytes.	RW	0x200

bytcnt

The number of bytes to be transferred.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704020

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
byte_count RW 0x200															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
byte_count RW 0x200															

bytcnt Fields

Bit	Name	Description	Access	Reset
31:0	byte_count	This value should be an integer multiple of the Block Size for block transfers. For undefined number of byte transfers, byte count should be set to 0. When byte count is set to 0, it is responsibility of host to explicitly send stop/abort command to terminate data transfer. Note: In SDIO mode, if a single transfer is greater than 4 bytes and non-DWORD-aligned, the transfer should be broken where only the last transfer is non-DWORD-aligned and less than 4 bytes. For example, if a transfer of 129 bytes must occur, then the driver should start at least two transfers; one with 128 bytes and the other with 1 byte.	RW	0x200

intmask

Allows Masking of Various Interrupts

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704024

Offset: 0x24

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit Fields

23	ccs_expected	<p>If the command expects Command Completion Signal (CCS) from the CE-ATA device, the software should set this control bit. SD/MMC sets Data Transfer Over (DTO) bit in RINTSTS register and generates interrupt to host if Data Transfer Over interrupt is not masked.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device</td> </tr> <tr> <td>0x1</td> <td>Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device	0x1	Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device	RW	0x0
Value	Description									
0x0	Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device									
0x1	Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device									

Bit	Name	Description	Access	Reset						
22	read_ceata_device	<p>Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers. Maximum value of I/O transmission delay can be no less than 10 seconds. SD/MMC should not indicate read data timeout while waiting for data from CE-ATA device.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device</td> </tr> <tr> <td>0x1</td> <td>Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device	0x1	Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device	RW	0x0
Value	Description									
0x0	Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device									
0x1	Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device									
21	update_clock_registers_only	<p>Following register values transferred into card clock domain: CLKDIV, CLRSRC, CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During normal command sequence, when update_clock_registers_only = 0, following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOUT, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s). When bit is set, there are no Command Done interrupts because no command is sent to SD_MMC_CEATA cards.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Normal command sequence</td> </tr> <tr> <td>0x1</td> <td>Do not send commands, just update clock register value into card clock domain</td> </tr> </tbody> </table>	Value	Description	0x0	Normal command sequence	0x1	Do not send commands, just update clock register value into card clock domain	RW	0x0
Value	Description									
0x0	Normal command sequence									
0x1	Do not send commands, just update clock register value into card clock domain									
20:16	card_number	Card number in use must always be 0.	RW	0x0						

Bit	Name	Description	Access	Reset						
15	send_initialization	<p>After power on, 80 clocks must be sent to the card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card. This bit should not be set for either of the boot modes (alternate or mandatory).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Do not send initialization sequence (80 clocks of 1) before sending this command</td> </tr> <tr> <td>0x1</td> <td>Send initialization sequence before sending this command</td> </tr> </tbody> </table>	Value	Description	0x0	Do not send initialization sequence (80 clocks of 1) before sending this command	0x1	Send initialization sequence before sending this command	RW	0x0
Value	Description									
0x0	Do not send initialization sequence (80 clocks of 1) before sending this command									
0x1	Send initialization sequence before sending this command									
14	stop_abort_cmd	<p>When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state. This is also applicable for Boot mode transfers. To Abort boot mode, this bit should be set along with CMD[26] = disable_boot. Note: If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Don't stop or abort command to stop current data transfer in progress</td> </tr> <tr> <td>0x1</td> <td>Stop or Abort command, intended to stop current data transfer in progress</td> </tr> </tbody> </table>	Value	Description	0x0	Don't stop or abort command to stop current data transfer in progress	0x1	Stop or Abort command, intended to stop current data transfer in progress	RW	0x0
Value	Description

Bit	Name	Description	Access	Reset																
30:28	dw_dma_multiple_transaction_size	<p>Burst size of multiple transaction; should be programmed same as DMA controller multiple-transaction-size SRC/DEST_MSIZE. The units for transfers is 32 bits. A single transfer would be signalled based on this value. Value should be sub-multiple of 512. Allowed combinations for MSize and TX_WMark.</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Msize 1 and TX_WMARK 1-1023</td></tr> <tr> <td>0x1</td><td>Msize 4 and TX_WMARK 256</td></tr> <tr> <td>0x2</td><td>Msize 8 and TX_WMARK 128</td></tr> <tr> <td>0x3</td><td>Msize 16 and TX_WMARK 64</td></tr> <tr> <td>0x5</td><td>Msize 1 and RX_WMARK 512</td></tr> <tr> <td>0x6</td><td>Msize 4 and RX_WMARK 128</td></tr> <tr> <td>0x7</td><td>Msize 8 and RX_WMARK 64</td></tr> </tbody> </table>	Value	Description	0x0	Msize 1 and TX_WMARK 1-1023	0x1	Msize 4 and TX_WMARK 256	0x2	Msize 8 and TX_WMARK 128	0x3	Msize 16 and TX_WMARK 64	0x5	Msize 1 and RX_WMARK 512	0x6	Msize 4 and RX_WMARK 128	0x7	Msize 8 and RX_WMARK 64	RW	0x0
Value	Description																			
0x0	Msize 1 and TX_WMARK 1-1023																			
0x1	Msize 4 and TX_WMARK 256																			
0x2	Msize 8 and TX_WMARK 128																			
0x3	Msize 16 and TX_WMARK 64																			
0x5	Msize 1 and RX_WMARK 512																			
0x6	Msize 4 and RX_WMARK 128																			
0x7	Msize 8 and RX_WMARK 64																			

Bit	Name	Description	Access	Reset
27:16	rx_wmark	FIFO threshold watermark level when receiving data to card. When FIFO data count reaches greater than this number, DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data. In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of host to read remaining bytes on seeing Data Transfer Done interrupt. In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: $RX_WMark \leq 1022$ Recommended: 511; means greater than $(FIFO_DEPTH/2) - 1$ NOTE: In DMA mode during CCS time-out, the DMA does not generate the request at the end of packet, even if remaining bytes are less than threshold. In this case, there will be some data left in the FIFO. It is the responsibility of the application to reset the FIFO after the CCS timeout.	RW	0x3FF
11:0	tx_wmark	FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number, DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated, regardless of threshold programming. In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, host is responsible for filling FIFO with only required remaining bytes (not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty). In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: $TX_WMark \geq 1$; Recommended: $FIFO_DEPTH/2 = 512$; (means less than or equal to 512)	RW	0x0

The hard processor system (HPS) provides a quad serial peripheral interface (SPI) flash controller for access to serial NOR flash devices. The quad SPI flash controller supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The quad SPI flash controller is based on Cadence Quad SPI Flash Controller (QSPI_FLASH_CTRL).

Features of the Quad SPI Flash Controller

The quad SPI flash controller supports the following features:

- Single, dual, and quad I/O commands
- Device frequencies up to 108 MHz⁰
- Direct access and indirect access modes
- External direct memory access (DMA) controller support for indirect transfers
- Configurable clock polarity and phase
- Supports 108 MHz (MAX) clock frequency for all protocols in single transfer rate (STR) mode.⁽⁵³⁾
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Read data capture tuning
- Local buffering with error correction code (ECC) logic for indirect transfers
- Up to four devices
- Supports the Micron N25Q512A (512 Mb, 108 MHz) and Micron N25Q00AA (1024 Mb, 108 MHz) Quad SPI flash memories that are verified working with the HPS
- eExecute-In-Place (XIP) mode

Related Information

[Supported Flash Devices for Cyclone V and Arria V SoC](#)

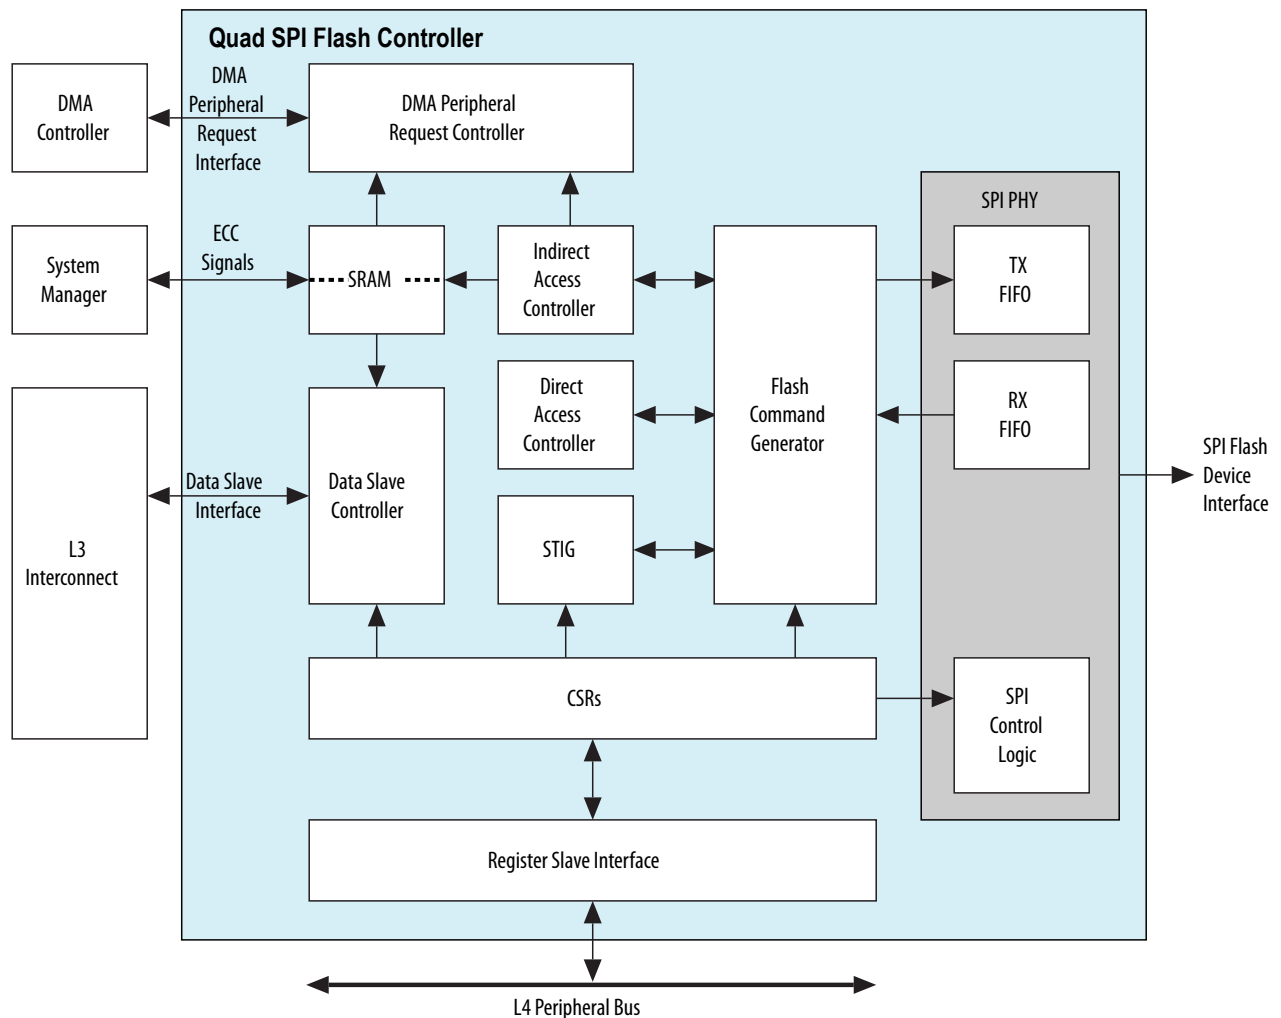

For more information, refer to the supported QSPI flash devices section on this page.

⁰ The quad SPI controller supports any device frequencies, but this speed is limited by the supported flash devices.

⁽⁵³⁾ This QSPI controller does not support Double Transfer Rate (DTR) mode.

Quad SPI Flash Controller Block Diagram and System Integration

Figure 16-1: Quad SPI Flash Controller Block Diagram and System Integration

The quad SPI controller consists of the following blocks and interfaces:

- Register slave interface—Slave interface that provides access to the control and status registers (CSRs)
- Data slave controller—Slave interface and controller that provides the following functionality:
 - Performs data transfers to and from the level 3 (L3) interconnect
 - Validates incoming accesses
 - Performs byte or half-word reordering
 - Performs write protection
 - Forwards transfer requests to direct and indirect controller
- Direct access controller—provides memory-mapped slaves direct access to the flash memory
- Indirect access controller—provides higher-performance access to the flash memory through local buffering and software transfer requests

- Software triggered instruction generator (STIG)—generates flash commands through the flash command register (`flashcmd`) and provides low-level access to flash memory
- Flash command generator—generates flash command and address instructions based on instructions from the direct and indirect access controllers or the STIG
- DMA peripheral request controller—issues requests to the DMA peripheral request interface to communicate with the external DMA controller
- SPI PHY—serially transfers data and commands to the external SPI flash devices

Interface Signals

The quad SPI controller provides four chip select outputs to allow control of up to four external quad SPI flash devices. The outputs serve different purposes depending on whether the device is used in single, dual, or quad operation mode. The following table lists the I/O pin use of the quad SPI controller interface signals for each operation mode.

Table 16-1: Interface Signals

Signal	Mode	Direction	Function
data[0]	Single	Output	Data output 0
	Dual or quad	Bidirectional	Data I/O 0
data[1]	Single	Input	Data input 0
	Dual or quad	Bidirectional	Data I/O 1

Functional Description of the Quad SPI Flash Controller

Overview

The quad SPI flash controller uses the register slave interface to select the operation modes and configure the data slave interface for data transfers. The quad SPI flash controller uses the data slave interface for direct and indirect accesses, and the register slave interface for software triggered instruction generator (STIG) operation and SPI legacy mode accesses.

Accesses to the data slave are forwarded to the direct or indirect access controller. If the access address is within the configured indirect address range, the access is sent to the indirect access controller.

Data Slave Interface

The quad SPI flash controller uses the data slave interface for direct, indirect, and SPI legacy mode accesses.

The data slave interface is 32 bits wide and permits byte, half-word, and word accesses. For write accesses, incrementing burst lengths of 1, 4, 8 and 16 are supported. For read accesses, all burst types and sizes are supported.

Direct Access Mode

Direct access mode is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming AMBA data slave interface access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and is serviced by the direct access controller.

Note: Accesses that use the direct access controller do not use the embedded SRAM.

Data Slave Remapping Example

Figure 16-2: Data Slave Remapping Example

To remap the data slave to access other 1 MB regions of the flash device, enable address remapping in the enable Arm AMBA advanced high speed bus (AHB) address remapping field (`enahbremap`) of the `cfg` register. All incoming data slave accesses remap to the offset specified in the remap address register (`remapaddr`).

The 20 LSBs of incoming addresses are used for accessing the 1 MB region and the higher bits are ignored.

Note: The quad SPI controller does not issue any error status for accesses that lie outside the connected flash memory space.

AHB

The data slave interface is throttled as the read or write burst is carried out. The latency is designed to be as small as possible and is kept to a minimum when the use of XIP read instructions are enabled.

FLASH erase operations, which may be required before a page write, are triggered by software using the documented programming interface. They are not issued automatically.

Once a page program cycle has been started, the QSPI Flash Controller will automatically poll for the write cycle to complete before allowing any further data slave interface accesses to complete. This is achieved by holding any subsequent AHB direct accesses in wait state.

Indirect Access Mode

In indirect access mode, flash data is temporarily buffered in the quad SPI controller's static RAM (SRAM). Software controls and triggers indirect accesses through the register slave interface. The controller transfers data through the data slave interface.

Indirect Read Operation

An indirect read operation reads data from the flash memory, places the data into the SRAM, and transfers the data to an external master through the data slave interface. The indirect read operations are controlled by the following registers:

- Indirect read transfer register (`indrdr`)
- Indirect read transfer watermark register (`indrdrwater`)
- Indirect read transfer start address register (`indrdrstaddr`)
- Indirect read transfer number bytes register (`indrdrnt`)
- Indirect address trigger register (`indrdrtrig`)

These registers need to be configured prior to issuing indirect read operations. The start address needs to be defined in the `indrdrstaddr` register and the total number of bytes to be fetched is specified in the `indrdrnt` register. Writing 1 to the start indirect read bit (`start`) of the `indrdr` register triggers the indirect read operation from the flash memory to populate the SRAM with the returned data.

To read data from the flash device into the SRAM, an external master issues 32-bit read transactions to the data slave interface. The address of the read access must be in the indirect address range. You can configure the indirect address through the `indrdrtrig` register. The external master can issue 32-bit reads until the last word of an indirect transfer. On the final read, the external master may issue a 32-bit, 16-bit or 8-bit read to complete the transfer. If there are less than four bytes of data to read on the last transfer, the external master can still issue a 32-bit read and the quad SPI controller will pad the upper bits of the response data with zeros.

Assuming the requested data is present in the SRAM at the time the data slave read is received by the quad SPI controller, the data is fetched from SRAM and the response to the read burst is achieved with minimum latency. If the requested data is not immediately present in the SRAM, the data slave interface enters a wait state until the data has been read from flash memory into SRAM. Once the data has been read from SRAM by the external master, the quad SPI controller frees up the associated resource in the SRAM. If the SRAM is full, reads on the SPI interface are backpressured until space is available in the SRAM. The quad SPI controller completes any current read burst, waits for SRAM to free up, and issues a new read burst at the address where the previous burst was terminated.

The processor can also use the SRAM fill level in the SRAM fill register (`sramfill`) to control when data should be fetched from the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indrwater` register. When the SRAM fill level passes the watermark level, the indirect transfer watermark interrupt is generated. You can disable this watermark feature by writing a value of all zeroes to the `indrwater` register.

For the final bytes of data read by the quad SPI controller and placed in the SRAM, if the watermark level is greater than zero, the indirect transfer watermark interrupt is generated even when the actual SRAM fill level has not risen above the watermark.

If the address of the read access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the read uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect read bit (`cancel`) of the `indr` register to 1. For more information, refer to the “Indirect Read Operation with DMA Disabled” section.

Related Information

[Indirect Read Operation with DMA Disabled](#) on page 16-16

Indirect Write Operation

An indirect write operation programs data from the SRAM to the flash memory. The indirect write operations are controlled by the following registers:

- Indirect write transfer register (`indwr`)
- Indirect write transfer watermark register (`indwrwater`)
- Indirect write transfer start address register (`indwrstaddr`)
- Indirect write transfer number bytes register (`indwrcnt`)
- `indaddrtrig` register

These registers need to be configured prior to issuing indirect write operations. The start address needs to be defined in the `indwrstaddr` register and the total number of bytes to be written is specified in the `indwrcnt` register. The start indirect write bit (`start`) of the `indwr` register triggers the indirect write operation from the SRAM to the flash memory.

To write data from the SRAM to the flash device, an external master issues 32-bit write transactions to the data slave. The address of the write access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit writes until the last word of an indirect transfer. On the final write, the external master may issue a 32-bit, 16-bit or 8-bit write to complete the transfer. If there are less than four bytes of data to write on the last transfer, the external master can still issue a 32-bit write and the quad SPI controller discards the extra bytes.

The SRAM size can limit the amount of data that the quad SPI controller can accept from the external master. If the SRAM is not full at the point of the write access, the data is pushed to the SRAM with minimum latency. If the external master attempts to push more data to the SRAM than the SRAM can accept, the quad SPI controller backpressures the external master with wait states. When the SRAM resource is freed up by pushing the data from SRAM to the flash memory, the SRAM is ready to receive more data from the external master. When the SRAM holds an equal or greater number of bytes than the size of a flash page, or when the SRAM holds all the remaining bytes of the current indirect transfer, the quad SPI controller initiates a write operation to the flash memory.

The processor can also use the SRAM fill level, in the `sramfill` register, to control when to write more data into the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indwrwater` register. When the SRAM fill level falls below the watermark level, an indirect transfer watermark interrupt is generated to tell the software to write the next page of data to the SRAM. Because the quad SPI controller initiates

non-end-of-data writes to the flash memory only when the SRAM contains a full flash page of data, you must set the watermark level to a value greater than one flash page to avoid the system stalling. You can disable this watermark feature by writing a value of all ones to the `indwrwater` register.

If the address of the write access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the write uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect write bit (`cancel`) of the `indwr` register to 1. For more information, refer to the “Indirect Write Operation with DMA Disabled” section.

Related Information

[Indirect Write Operation with DMA Disabled](#) on page 16-17

Consecutive Reads and Writes

It is possible to trigger two indirect operations at a time by triggering the `start` bit of the `indr` or `indwr` register twice in short succession. The second operation can be triggered while the first operation is in progress. For example, software may trigger an indirect read or write operation while an indirect write operation is in progress. The corresponding start and count registers must be configured properly before software triggers each transfer operation.

This approach allows for a short turnaround time between the completion of one indirect operation and the start of a second operation. Any attempt to queue more than two operations causes the indirect read reject interrupt to be generated.

SPI Legacy Mode

SPI legacy mode allows software to access the internal TX FIFO and RX FIFO buffers directly, thus bypassing the direct, indirect and STIG controllers. Software accesses the TX FIFO and RX FIFO buffers by writing any value to any address through the data slave while legacy mode is enabled. You can enable legacy mode with the legacy IP mode enable bit (`enlegacyip`) of the `cfg` register.

Legacy mode allows the user to issue any flash instruction to the flash device, but imposes a heavy software overhead in order to manage the fill levels of the FIFO buffers effectively. The legacy SPI mode is bidirectional in nature, with data continuously being transferred both directions while the chip select is enabled. If the driver only needs to read data from the flash device, dummy data must be written to ensure the chip select stays active, and vice versa for write transactions.

For example, to perform a basic read of four bytes to a flash device that has three address bytes, software must write a total of eight bytes to the TX FIFO buffer. The first byte would be the instruction opcode, the next three bytes are the address, and the final four bytes would be dummy data to ensure the chip select stays active while the read data is returned. Similarly, because eight bytes were written to the TX FIFO buffer, software should expect eight bytes to be returned in the RX FIFO buffer. The first four bytes of this would be discarded, leaving the final four bytes holding the data read from the device.

Because the TX FIFO and RX FIFO buffers are four bytes deep each, software must maintain the FIFO buffer levels to ensure the TX FIFO buffer does not underflow and the RX FIFO buffer does not overflow. Interrupts are provided to indicate when the fill levels pass the watermark levels, which are configurable through the TX threshold register (`txtresh`) and RX threshold register (`rxtrash`).

Register Slave Interface

The quad SPI flash controller uses the register slave interface to configure the quad SPI controller through the quad SPI configuration registers, and to access flash memory under software control, through the `flashcmd` register in the STIG.

STIG Operation

The Software Triggered Instruction Generator (STIG) is used to access the volatile and non-volatile configuration registers, the legacy SPI status register, and other status and protection registers. The STIG also is used to perform ERASE functions. The direct and indirect access controllers are used only to transfer data. The `flashcmd` register uses the following parameters to define the command to be issued to the flash device:

- Instruction opcode
- Number of address bytes
- Number of dummy bytes
- Number of write data bytes
- Write data
- Number of read data bytes

The address is specified through the flash command address register (`flashcmdaddr`). Once these settings have been specified, software can trigger the command with the execute command field (`execcmd`) of the `flashcmd` register and wait for its completion by polling the command execution status bit (`cmdexecstat`) of the `flashcmd` register. A maximum of eight data bytes may be read from the flash command read data lower (`flashcmdrddatalo`) and flash command read data upper (`flashcmdrddataup`) registers or written to the flash command write data lower (`flashcmdwrdata1o`) and flash command write data upper (`flashcmdwrdataup`) registers per command.

Commands issued through the STIG have a higher priority than all other read accesses and therefore interrupt any read commands being requested by the direct or indirect controllers. However, the STIG does not interrupt a write sequence that may have been issued through the direct or indirect access controller. In these cases, it might take a long time for the `cmdexecstat` bit of the `flashcmd` register indicates the operation is complete.

Note: Intel recommends using the STIG instead of the SPI legacy mode to access the flash device registers and perform erase operations.

Local Memory Buffer

The SRAM local memory buffer is a 128 by 32-bit (512 total bytes) memory and includes support for error correction code (ECC). The ECC logic provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes.

You must initialize memory data before enabling ECC to prevent spurious ECC interrupts when you enable ECC for the first time.

Follow these steps to enable ECC:

1. Turn on the ECC hardware, but disable the interrupts.
2. Initialize the SRAM in the NAND.
3. Clear the ECC event bits, because these bits may have become asserted after Step 1.
4. Enable the ECC interrupts now that the ECC bits have been set.

The SRAM has two partitions, with the lower partition reserved for indirect read operations and the upper partition reserved for indirect write operations, as shown in [Figure 16-1](#). The size of each partition is specified in the SRAM partition register (`srampart`), based on 32-bit word sizes. The number of locations allocated to indirect read is (`srampart + 1`); and the number of locations allocated to indirect write is $(128 - \text{srampart})^{(54)}$. For example, to specify four bytes of storage, write the value 1. The value written to the indirect read partition size field (`addr`) defines the number of entries reserved for indirect read operations. For example, write the value 32 (0x20) to partition the 128-entry SRAM to 32 entries (25%) for read usage and 96 entries (75%) for write usage.

[System Manager](#) on page 6-1

DMA Peripheral Request Controller

The DMA peripheral request controller is only used for the indirect mode of operation where data is temporarily stored in the SRAM. The quad SPI flash controller uses the DMA peripheral request interface to trigger the external DMA into performing data transfers between memory and the quad SPI controller.

There are two DMA peripheral request interfaces, one for indirect reads and one for indirect writes. The DMA peripheral request controller can issue two types of DMA requests, single or burst, to the external DMA. The number of bytes for each single or burst request is specified in the number of single bytes (`numsglreqbytes`) and number of burst bytes (`numburstreqbytes`) fields of the DMA peripheral register (`dmaper`). The DMA peripheral request controller splits the total amount of data to be transferred into a number of DMA burst and single requests by dividing the total number of bytes by the number of bytes specified in the burst request, and then dividing the remainder by the number of bytes in a single request.

Note: When programming the DMA controller, the burst request size must match the burst request size set in the quad SPI controller to avoid quickly reaching an overflow or underflow condition.

For indirect reads, the DMA peripheral request controller only issues DMA requests after the data has been retrieved from flash memory and written to SRAM. The rate at which DMA requests are issued depends on the watermark level. The `indrwater` register defines the minimum fill level in bytes at which the DMA peripheral request controller can issue the DMA request. The higher this number is, the more data that must be buffered in SRAM before the external DMA moves the data. When the SRAM fill level passes the watermark level, the transfer watermark reached interrupt is generated.

For example, consider the following conditions:

- The total amount of data to be read using indirect mode is 256 bytes
- The SRAM watermark level is set at 128 bytes
- Software configures the burst type transfer size to 64 bytes

Under these conditions, the DMA peripheral request controller issues the first DMA burst request when the SRAM fill level passes 128 bytes (the watermark level). The DMA peripheral request controller triggers consecutive DMA burst requests as long as there is sufficient data in the SRAM to perform burst type requests. In this example, DMA peripheral request controller can issue at least two consecutive DMA burst requests to transfer a total of 128 bytes. If there is sufficient data in the SRAM, the DMA peripheral request controller requests the third DMA burst immediately. Otherwise the DMA peripheral request controller waits for the SRAM fill level to pass the watermark level again to trigger the next burst request. When the watermark level is triggered, there is sufficient data in the SRAM to perform the third and fourth burst requests to complete the entire transaction.

For the indirect writes, the DMA peripheral request controller issues DMA requests immediately after the transfer is triggered and continues to do so until the entire indirect write transfer has been transferred. The

⁽⁵⁴⁾ You cannot allocate all of the SRAM for writes.

rate at which DMA requests are issued depends on the watermark level. The `indwrwater` register defines the maximum fill level in bytes at which the controller can issue the first DMA burst or single request. When the SRAM fill level falls below the watermark level, the transfer watermark reached interrupt is generated. When there is one flash page of data in the SRAM, the quad SPI controller initiates the write operation from SRAM to the flash memory.

Software can disable the DMA peripheral request interface with the `endma` field of the `cfg` register. If a master other than the DMA performs the data transfer for indirect operations, the DMA peripheral request interface must be disabled. By default, the indirect watermark registers are set to zero, which means the DMA peripheral request controller can issue DMA request as soon as possible.

For more information about the HPS DMA controller, refer to the *DMA Controller* chapter in volume 3 of the Cyclone® V Device Handbook.

Arbitration between Direct/Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

1. The Indirect Access Write
2. The Direct Access Write
3. The STIG
4. The Direct Access Read
5. The Indirect Access Read

Each controller is back pressured while waiting to be serviced.

Configuring the Flash Device

For read and write accesses, software must initialize the device read instruction register (`devrd`) and the device write instruction register (`devwr`). These registers include fields to initialize the instruction opcodes that should be used as well as the instruction type, and whether the instruction uses single, dual or quad pins for address and data transfer. To ensure the quad SPI controller can operate from a reset state, the opcode registers reset to opcodes compatible with single I/O flash devices.

The quad SPI flash controller uses the instruction transfer width field (`instwidth`) of the `devrd` register to set the instruction transfer width for both reads and writes. There is no `instwidth` field in the `devwr` register. If instruction type is set to dual or quad mode, the address transfer width (`addrwidth`) and data transfer width (`datawidth`) fields of both registers are redundant because the address and data type is based on the instruction type. Thus, software can support the less common flash instructions where the opcode, address, and data are sent on two or four lanes. For most instructions, the opcodes are sent serially to the flash device, even for dual and quad instructions. One of the flash devices that supports instructions that can send the opcode over two or four lanes is the Micron N25Q128. For reference, [Table 16-2](#) and [Table 16-3](#) show how software should configure the quad SPI controller for each specific read and write instruction, respectively, supported by the Micron N25Q128 device.

Table 16-2: Quad SPI Configuration for Micron N25Q128 Device (Read Instructions)

Dual command fast program (DCFP)	2	2	2	1	Don't care	Don't care
Quad command fast program (QCFP)	4	4	4	2	Don't care	Don't care

Write Request

The `Write Enable Latch (WEL)` bit within the flash device itself must be high before a write sequence can be issued. The command generator automatically issues the `Write Enable (WREN)` instruction to set the `WEL` bit before triggering a write command through the direct or indirect access controllers. When write requests are no longer received and all outstanding requests have been sent, then the flash device starts the page program write cycle. Any incoming request at this time is held in wait states until the cycle has completed. The controller automatically polls the flash device `Read Status Register (RDSR)` to identify when the write cycle has completed. This continues until the `Write In Progress` bit and `WEL` bit have cleared to zero. The op-code for the `WREN` instruction is typically `0x06h` and `0x05h` for the `RDSR` instruction.

Note: These op-codes are common between devices.

XIP Mode

The quad SPI controller supports XIP mode, if the flash devices support XIP mode. Depending on the flash device, XIP mode puts the flash device in read-only mode, reducing command overhead.

The quad SPI controller must instruct the flash device to enter XIP mode by sending the mode bits. When the `enter XIP mode on next read bit (enterxipnextrd)` of the `cfg` register is set to 1, the quad SPI controller and the flash device are ready to enter XIP mode on the next read instruction. When the `enter XIP mode immediately bit (enterxipimm)` of the `cfg` register is set to 1, the quad SPI controller and flash device enter XIP mode immediately.

When the `enterxipnextrd` or `enterxipimm` bit of the `cfg` register is set to 0, the quad SPI controller and flash device exit XIP mode on the next read instruction. For more information, refer to the “*XIP Mode Operations*” section.

Related Information

[XIP Mode Operations](#) on page 16-18

Write Protection

You can program the controller to write protect a specific region of the flash device. The protected region is defined as a set of blocks, specified by a starting and ending block. Writing to an area of protected flash region memory generates an error and triggers an interrupt.

You define the block size by specifying the number of bytes per block through the number of bytes per block field (`bytespersubsector`) of the device size register (`devsz`). The lower write protection register (`lowwrprot`) specifies the first flash block in the protected region. The upper write protection register (`upprprot`) specifies the last flash block in the protected region.

The write protection enable bit (`en`) of the write protection register (`wrprot`) enables and disables write protection. The write protection inversion bit (`inv`) of the `wrprot` register flips the definition of protection so that the region specified by `lowwrprt` and `upprprt` is unprotected and all flash memory outside that region is protected.

Data Slave Sequential Access Detection

The quad SPI flash controller detects sequential accesses to the data slave interface by comparing the current access with the previous access. An access is sequential when it meets the following conditions:

- The address of the current access sequentially follows the address of the previous access.
- The direction of the current access (read or write) is the same as previous access.
- The size of the current access (byte, half-word, or word) is the same as previous access.

When the access is detected as nonsequential, the sequential access to the flash device is terminated and a new sequential access begins. Intel recommends accessing the data slave sequentially. Sequential access has less command overhead, and therefore, increases data throughput.

Clocks

There are two clock inputs to the quad SPI controller: `l4_mp_clk` and `qspi_ref_clk`; and one clock output: `qspi_clk`. The quad SPI flash controller uses the `l4_mp_clk` clock to clock the data slave transfers and register slave accesses. The `qspi_ref_clk` clock is the reference clock for the quad SPI controller and is used to serialize the data and drive the external SPI interface. The `qspi_clk` clock is the clock source for the connected flash devices.

The following is true for the following reference clocks:

- `qspi_ref_clk` should be greater than `l4_mp_clk`
- `qspi_ref_clk` must be greater than two times `qspi_clk`

The `qspi_clk` clock is derived by dividing down the `qspi_ref_clk` clock by the baud rate divisor field (`bauddiv`) of the `cfg` register.

Related Information

[Clock Manager](#) on page 3-1

Resets

A single reset signal (`qspi_flash_rst_n`) is provided as an input to the quad SPI controller. The reset manager drives the signal on a cold or warm reset.

Related Information

[Reset Manager](#) on page 4-1

Taking the Quad SPI Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

All interrupt sources are combined to create a single level-sensitive, active-high interrupt (`qspi_intr`). Software can determine the source of the interrupt by reading the interrupt status register (`irqstat`). By default, the interrupt source is cleared when software writes a one (1) to the interrupt status register. The interrupts are individually maskable through the interrupt mask register (`irqmask`). [Table 16-4](#) lists the interrupt sources in the `irqstat` register.

Table 16-4: Interrupt Sources in the `irqstat` Register

Interrupt Source	Description
Underflow detected	When 0, no underflow has been detected. When 1, the data slave write data is being supplied too slowly. This situation can occur when data slave write data is being supplied too slowly to keep up with the requested write operation. This bit is reset only by a system reset and cleared only when a 1 is written to it.
Indirect operation complete	The controller has completed a triggered indirect operation.
Indirect read reject	An indirect operation was requested but could not be accepted because two indirect operations are already in the queue.
Protected area write attempt	A write to a protected area was attempted and rejected.
Illegal data slave access detected	An illegal data slave access has been detected. Data slave wrapping bursts and the use of split and retry accesses can cause this interrupt. It is usually an indicator that soft masters in the FPGA fabric are attempting to access the HPS in an unsupported way.
Transfer watermark reached	The indirect transfer watermark level has been reached.
Receive overflow	This condition occurs only in legacy SPI mode. When 0, no overflow has been detected. When 1, an overflow to the RX FIFO buffer has occurred. This bit is reset only by a system reset and cleared to zero only when this register is written to. If a new write to the RX FIFO buffer occurs at the same time as a register is read, this flag remains set to 1.

Interrupt Source	Description
TX FIFO not full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is full. When 1, the TX FIFO buffer is not full.
TX FIFO full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is not full. When 1, the TX FIFO buffer is full.
RX FIFO not empty	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is empty. When 1, the RX FIFO buffer is not empty.
RX FIFO full	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is not full. When 1, the RX FIFO buffer is full.
Indirect read partition overflow	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation

Quad SPI Flash Controller Programming Model

Setting Up the Quad SPI Flash Controller

The following steps describe how to set up the quad SPI controller:

1. Wait until any pending operation has completed.
2. Disable the quad SPI controller with the quad SPI enable field (*en*) of the *cfg* register.
3. Update the *instwidth* field of the *devrd* register with the instruction type you wish to use for indirect and direct writes and reads.
4. If mode bit enable bit (*enmodebits*) of the *devrd* register is enabled, update the mode bit register (*modebit*).
5. Update the *devsz* register as needed.
Parts or all of this register might have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used.
6. Update the device delay register (*delay*).
This register allows the user to adjust how the chip select is driven after each flash access. Each device may have different timing requirements. If the serial clock frequency is increased, these timing requirements become more critical. The numbers specified in this register are based on the period of the *qspi_ref_clk* clock. For example, some devices need 50 ns minimum time before the slave select can be reasserted after it has been deasserted. When the device is operating at 100 MHz, the clock period is 10 ns, so 40 ns extra is required. If the *qspi_ref_clk* clock is running at 400 MHz (2.5 ns period), specify a value of at least 16 to the clock delay for chip select deassert field (*nss*) of the *delay* register.
7. Update the *remapaddr* register as needed.

This register only affects direct access mode.

8. Set up and enable the write protection registers (`wrprot`, `lowwrprot`, and `upwrprot`) when write protection is required.
9. Enable required interrupts through the `irqmask` register.
10. Set up the `bauddiv` field of the `cfg` register to define the required clock frequency of the target device.
11. Update the read data capture register (`rddatacap`) if you need to change the auto-filled value.

The Cyclone V pre-loader fills in this register with a value when the calibration routine is run at boot-up. To modify this value, you may refer to the "QSPI Timing" section in the *Cyclone V Data Sheet*. This register delays when the read data is captured and can help when the read data path from the device to the quad SPI controller is long (which is relative to the hardware layout and design) and the device clock frequency is high.

12. Enable the quad SPI controller with the `en` field of the `cfg` register.

Indirect Read Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA disabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 16-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the `irqmask` register.
6. If the watermark level is used, set the SRAM watermark level through the `indrwater` register.
7. Start the indirect read operation by setting the `start` field of the `indr` register to 1.
8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient data in the SRAM.
9. Issue a read transaction to the indirect address to access the SRAM. Repeat [step 8](#) if more read transactions are needed to complete the indirect read transfer.
10. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the indirect completion status bit (`ind_ops_done_status`) of the `indr` register.

Related Information

Indirect Read Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA enabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 16-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.

5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indrwater` register to control the rate DMA requests are issued.
7. Start an indirect read access by setting the `start` field of the `indr` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the `ind_ops_done_status` field of the `indr` register.

Related Information

Indirect Write Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA disabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 16-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set up the number of bytes to be transferred in the `indwrcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the interrupt mask register (`irqmask`).
6. Start the indirect write operation by setting the `start` field of the `indwr` register to 1.
7. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient space in the SRAM.
8. Issue a write transaction to the indirect address to write one flash page of data to the SRAM. Repeat [step 8](#) if more write transactions are needed to complete the indirect write transfer. The final write may be less than one page of data.

Indirect Write Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA enabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 16-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set the number of bytes to be transferred in the `indcnt` field of the `indwr` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indwrwater` register to control the rate DMA requests are issued. The value set must be greater than one flash page. For more information, refer to the [Indirect Write Operation](#) on page 16-6 section.
7. Start the indirect write access by setting the `start` field of the `indirwr` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect write operation has completed or poll the completion status of the indirect write operation through the `ind_ops_done_status` field of the `indwr` register.

XIP Mode Operations

XIP mode is supported in most SPI flash devices. However, flash device manufacturers do not use a consistent standard approach. Most use signature bits that are sent to the device immediately following the address bytes. Some devices use signature bits and also require a flash device configuration register write to enable XIP mode.

Entering XIP Mode

Micron Quad SPI Flash Devices with Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device with support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x80.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Micron Quad SPI Flash Devices without Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device without support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses gets sent to the flash device.
3. Ensure XIP mode is enabled in the flash device by setting the volatile configuration register (VCR) bit 3 to 1. Use the `flashcmd` register to issue the VCR write command.
4. Set the XIP mode bits in the `modebit` register to 0x00.
5. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
6. Re-enable the direct access controller and, if required, the indirect access controller.

Winbond Quad SPI Flash Devices

To enter XIP mode in a Winbond quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x20.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Spansion Quad SPI Flash Devices

To enter XIP mode a Spansion quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to `0xA0`.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Exiting XIP Mode

To exit XIP mode, perform the following steps:

1. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
2. Restore the mode bits to the values before entering XIP mode, depending on the flash device and manufacturer.
3. Set the `enterxipnextrd` bit of the `cfg` register to 0.

The flash device must receive a read instruction before it can disable its internal XIP mode state. Thus, XIP mode internally stays active until the next read instruction is serviced. Ensure that XIP mode is disabled before the end of any read sequence.

XIP Mode at Power on Reset

Some flash devices can be XIP-enabled as a nonvolatile configuration setting, allowing the flash device to enter XIP mode at power-on reset (POR) without software intervention. Software cannot discover the XIP state at POR through flash status register reads because an XIP-enabled flash device can only be accessed through the XIP read operation. If you know the device may enter XIP mode at POR, have your initial boot software configure the `modebit` register and set the `enterxipimm` bit of the `cfg` register to 1.

If you do not know in advance whether or not the device may enter XIP mode at POR, have your initial boot software issue an XIP mode exit command through the `flashcmd` register, then follow the steps in the “*Entering XIP Mode*” section. Software must be aware of the mode bit requirements of the device, because XIP mode entry and exit varies by device.

Bit	Name	Description	Access	Reset						
17	enterxipnextrd	<p>If XIP is enabled, then setting to disabled will cause the controller to exit XIP mode on the next READ instruction. If XIP is disabled, then setting to enabled will inform the controller that the device is ready to enter XIP on the next READ instruction. The controller will therefore send the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register after the controller has ensured the FLASH device has been configured to be ready to enter XIP mode. Note : To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only AFTER the next READ instruction is executed. Software should therefore ensure that at least one READ instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Enter XIP Mode on next READ instruction</td> </tr> <tr> <td>0x0</td> <td>Exit XIP Mode on next READ instruction</td> </tr> </tbody> </table>	Value	Description	0x1	Enter XIP Mode on next READ instruction	0x0	Exit XIP Mode on next READ instruction	RW	0x0

Reserved												level RW 0x1			

rxthresh Fields

Bit	Name	Description	Access	Reset
3:0	level	Defines the level at which the receive FIFO not empty interrupt is generated	RW	0x1

irqstat

The status fields in this register are set when the described event occurs and the interrupt is enabled in the mask register. When any of these bit fields are set, the interrupt output is asserted high. The fields are each cleared by writing a 1 to the field. Note that bit fields 7 thru 11 are only valid when legacy SPI mode is active.

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705040

Offset: 0x40

Access: RW

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Bit	Name	Description	Access	Reset						
12	indsramfull	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation <table border="0"> <tr> <td style="text-align: center;">Value</td> <td style="text-align: center;">Description</td> </tr> <tr> <td>0x1</td> <td>SRAM is full</td> </tr> <tr> <td>0x0</td> <td>SRAM is not full</td> </tr> </table>	Value	Description	0x1	SRAM is full	0x0	SRAM is not full	RW	0x0
Value	Description									
0x1	SRAM is full									
0x0	SRAM is not full									
11	rxfull	Indicates that the receive FIFO is full or not. Only relevant in SPI legacy mode. <table border="0"> <tr> <td style="text-align: center;">Value</td> <td style="text-align: center;">Description</td> </tr> <tr> <td>0x0</td> <td>Receive FIFO Not Full</td> </tr> <tr> <td>0x1</td> <td>Receive FIFO Full</td> </tr> </table>	Value	Description	0x0	Receive FIFO Not Full	0x1	Receive FIFO Full	RW	0x0
Value	Description									
0x0	Receive FIFO Not Full									
0x1	Receive FIFO Full									
10	rxthreshcmp	Indicates the number of entries in the receive FIFO with respect to the threshold specified in the RXTHRESH register. Only relevant in SPI legacy mode. <table border="0"> <tr> <td style="text-align: center;">Value</td> <td style="text-align: center;">Description</td> </tr> <tr> <td>0x0</td> <td>FIFO has <= RXTHRESH entries</td> </tr> <tr> <td>0x1</td> <td>FIFO has > RXTHRESH entries</td> </tr> </table>	Value	Description	0x0	FIFO has <= RXTHRESH entries	0x1	FIFO has > RXTHRESH entries	RW	0x0
Value	Description									
0x0	FIFO has <= RXTHRESH entries									
0x1	FIFO has > RXTHRESH entries									

Bit	Name	Description	Access	Reset						
9	txfull	Indicates that the transmit FIFO is full or not. Only relevant in SPI legacy mode. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmit FIFO Not Full</td> </tr> <tr> <td>0x1</td> <td>Transmit FIFO Full</td> </tr> </tbody> </table>	Value	Description	0x0	Transmit FIFO Not Full	0x1	Transmit FIFO Full	RW	0x0
Value	Description									
0x0	Transmit FIFO Not Full									
0x1	Transmit FIFO Full									
8	txthreshcmp	Indicates the number of entries in the transmit FIFO with respect to the threshold specified in the TXTHRESH register. Only relevant in SPI legacy mode. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>FIFO has > TXTHRESH entries</td> </tr> <tr> <td>0x1</td> <td>FIFO has <= TXTHRESH entries</td> </tr> </tbody> </table>	Value	Description	0x0	FIFO has > TXTHRESH entries	0x1	FIFO has <= TXTHRESH entries	RW	0x1
Value	Description									
0x0	FIFO has > TXTHRESH entries									
0x1	FIFO has <= TXTHRESH entries									
7	rxover	This should only occur in Legacy SPI mode. Set if an attempt is made to push the RX FIFO when it is full. This bit is reset only by a system reset and cleared only when this register is read. If a new push to the RX FIFO occurs coincident with a register read this flag will remain set. 0 : no overflow has been detected. 1 : an overflow has occurred. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Receive Overflow</td> </tr> <tr> <td>0x0</td> <td>No Receive Overflow</td> </tr> </tbody> </table>	Value	Description	0x1	Receive Overflow	0x0	No Receive Overflow	RW	0x0
Value	Description									
0x1	Receive Overflow									
0x0	No Receive Overflow									
6	indxfrlvl	Indirect Transfer Watermark Level Reached <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Water level reached</td> </tr> <tr> <td>0x0</td> <td>No water level reached</td> </tr> </tbody> </table>	Value	Description	0x1	Water level reached	0x0	No water level reached	RW	0x0
Value	Description									
0x1	Water level reached									
0x0	No water level reached									
5	illegalacc	Illegal AHB access has been detected. AHB wrapping bursts and the use of SPLIT/RETRY accesses will cause this error interrupt to trigger. <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Illegal AHB attempt</td> </tr> <tr> <td>0x0</td> <td>No Illegal AHB attempt</td> </tr> </tbody> </table>	Value	Description	0x1	Illegal AHB attempt	0x0	No Illegal AHB attempt	RW	0x0
Value	Description									
0x1	Illegal AHB attempt									
0x0	No Illegal AHB attempt									

Bit	Name	Description	Access	Reset						
4	protwrattempt	Write to protected area was attempted and rejected. <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x1</td> <td>Write Attempt to protected area</td> </tr> <tr> <td>0x0</td> <td>No Write Attempt</td> </tr> </table>	Value	Description	0x1	Write Attempt to protected area	0x0	No Write Attempt	RW	0x0
Value	Description									
0x1	Write Attempt to protected area									
0x0	No Write Attempt									
3	indrdreject	Indirect operation was requested but could not be accepted. Two indirect operations already in storage. <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x1</td> <td>Indirect Operation Requested</td> </tr> <tr> <td>0x0</td> <td>No Indirect Operation</td> </tr> </table>	Value	Description	0x1	Indirect Operation Requested	0x0	No Indirect Operation	RW	0x0
Value	Description									
0x1	Indirect Operation Requested									
0x0	No Indirect Operation									
2	indopdone	Controller has completed last triggered indirect operation <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x1</td> <td>Completed Indirect Operation</td> </tr> <tr> <td>0x0</td> <td>No Indirect Operation</td> </tr> </table>	Value	Description	0x1	Completed Indirect Operation	0x0	No Indirect Operation	RW	0x0
Value	Description									
0x1	Completed Indirect Operation									
0x0	No Indirect Operation									
1	underflowdet	An underflow is detected when an attempt to transfer data is made when the transmit FIFO is empty. This may occur when the AHB write data is being supplied too slowly to keep up with the requested write operation. This bit is reset only by a system reset and cleared only when the register is read. <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x1</td> <td>Underflow</td> </tr> <tr> <td>0x0</td> <td>No Underflow</td> </tr> </table>	Value	Description	0x1	Underflow	0x0	No Underflow	RW	0x0
Value	Description									
0x1	Underflow									
0x0	No Underflow									

irqmask

If disabled, the interrupt for the corresponding interrupt status register bit is disabled. If enabled, the interrupt for the corresponding interrupt status register bit is enabled.
